THE PROBLEMS WHICH MOST PERPLEX THE SURGEON.[1]

BY ROSWELL PARK, A.M., M.D.,

PROFESSOR OF SURGERY, MEDICAL DEPARTMENT, UNIVERSITY [illegible]

THE more conversant one becomes with the literature and accumulated knowledge of others concerning the topics which especially interest him, and the more he pursues his studies within restricted lines, the more difficult it becomes to select a subject of which he may legitimately treat before such an audience as this. It is therefore with not a little hesitation, and yet with the highest appreciation of the honor done me in inviting me to address you on this occasion, that I have concluded to invite your attention to some of the problems which the medical profession as a class, and particularly those who practise surgery, are to-day most often called upon to confront, which still seem so obscure that when asked for explanations we have to confess absolute ignorance, and state that we sadly need light from any and every source.

We have a right to view with the greatest satisfaction and pride the progress which has been made both in the theory and practice of surgery, and particularly in that branch of general surgery spoken of as surgical pathology. And just here I may be permitted to remind you that, according to the best standards of the day, pathology is not distinct from but must be a part of surgery—else would the surgeon lose the explanation of both the lesion which he is treating and of the reason for his treatment. I think, then, that of all the factors that can be mentioned as having conspired to put surgery where it is to-day, the most conspicuous is the recognition which surgeons have given to surgical pathology. In consequence I may repeat here the statement which I often make, and which may well challenge contradiction—"that of all the branches of applied science, none has made more rapid progress during the last twenty-five years than surgery, save only electricity."

It being admittedly then so impossible to dissociate theory from practice, the active thinker finds himself sadly hampered in treating actual disease, when he fails to understand either its nature or the bodily conditions which have permitted its occurrence, or both. Among the so-called surgical diseases we are familiar with the active causative agents in nearly all instances, but we are far from familiar with those physical conditions of the body which seem at one time to invite and at another prevent infection. This might bring up before us the whole question of susceptibility and immunity, over which physicians and surgeons must undoubtedly vex themselves for yet many years before the intricate problems involved are regarded as settled—if, indeed, a happy solution be ever reached. Upon these subjects I have more than once addressed my colleagues in various other societies, and do not now purpose to take them up again. Nevertheless there is one aspect even of these questions which it might be well to present to you as one of universal interest, one which calls for much careful study, in which the young workers of this or any other society might profitably concern themselves.

I have long been convinced that the susceptibility and immunity of a patient about to undergo a given operation are influenced not alone by the state of his excretory organs and his freedom from toxæmia of any description, but also by the anæsthetic required for the successful and easy performance of the same, and its effects as manifested through his own blood. We have had many careful observations made with reference to the effect of chloroform and ether upon the action of the heart, the blood pressure, etc., and their effect upon the kidneys and the elimination of the drug, as well as upon the temperature of the individual.

Illustrative of careful studies of this kind is the research concerning the latter recently published by Dr. Dudley Allen,[2] of Cleveland, by all of which our clinical knowledge concerning the effect of anæsthetics has been materially augmented. I cannot conceive it possible, however, that the amount of chloroform, for example, required to keep a patient anæsthetized for an hour, and which is still being eliminated at the end of the second day, as evinced by the odor emanating from both his lungs and person, can be so long retained in solution in his blood without more or less perceptibly affecting its germicidal properties, as well as perhaps some of the other physical attributes pertaining to this vital fluid. It may be that absence of this interference with its powers may account for escape from serious infection after extensive accidental lesions, while fatal infection occurs sometimes, in spite of great caution observed, during the performance of operations under anæsthesia. To this conviction I confess I have been moved not so much by experimental evidence as by clinical observations and certain general knowledge. What is needed in this regard is exact laboratory investigation, by which, for instance, the blood of a healthy patient, about to undergo some protracted operation, should be first examined a day or two beforehand, by the spectroscope and by several other laboratory tests, to determine the exact proportion of hæmoglobin and of red and white corpuscles, while it should also be carefully tested regarding its bactericidal powers. This entire and elaborate series of examinations should then be repeated some six, twelve, and twenty-four hours after the operation, while in a general way the anæsthetic employed and the amount of blood lost should be noted. I am willing to venture a prophecy that after a sufficient number of such researches have been carefully collated important deductions can be made, and that it will be found that prolonged anæsthesia does increase susceptibility to infection or reduce immunity, as you may like to put it; which facts having been established, we may then be in better position to fortify our patients against this now known and recognized danger. All of this investigation, however, will require tremendous time and patience on the part of more than one observer, and can be carried on only in some institution well

[1] The address in surgery before the Michigan State Medical Society, Grand Rapids, May 13, 1897.

[2] American Journal of the Medical Sciences, March, 1897.

equipped for the purpose. There is here, I am sure, a chance for young men to distinguish themselves if they will devote themselves to the task.

One of the most important problems before us to-day seems to be with regard to the actual cause of death in numerous cases of acute and gangrenous appendicitis, in which almost from the outset the expressions of toxæmia and sepsis are overwhelming. I have seen too many cases of this kind not to be conversant with the gross findings. Nevertheless I am still unable, as I think is every one else, really to explain the intense toxicity that characterizes them. This is not merely a question of stercoræmia from intestinal paralysis, which undoubtedly makes up a considerable part of such a case, but to this there is added something more overpowering and not included in the ordinary expressions of intestinal auto-intoxication. I know of no chemical researches which have been made upon the pus removed from large peri-appendical abscesses, but for my own part suspect that some of the sulphur compounds generated under these circumstances, having more or less to do with the allyl group, may be blamed for a part of the poisoning of which I am speaking.

Much may be explained in one direction by the coprostatic acute obstruction so frequently met with in these cases, and to which I believe I was one of the first to call attention. Indeed, in the light of our present knowledge, this form of obstruction, due to causes proceeding from the appendix, needs to be mentioned as by all means the most common form of acute strangulation of the bowels, although it is one too often overlooked by the profession at large, and not figuring with its deserved prominence even in recent text-books and literature. This is due in some cases to intestinal paralysis, in others to adhesions and interference with motility. If personal experience may be in this matter any criterion, I should say in all cases of acute strangulation accompanied by septic symptoms, and in the absence of something definite pointing to lesion in another locality, the wisest and in the long run the safest course would be to make the preliminary incision in the right iliac fossa. In so doing the surgeon will be right four times for every error that he may make.

The extreme toxicity of all cases of putrid peritonitis is not to be explained alone by the capacity of the peritoneum for absorption. Neither is this toxicity made known by general symptoms alone. The poisons so rapidly generated seem noxious to all the cells with which they come into contact; hence gangrene or necrosis of involved surfaces appears very early. Numerous expressions of this fact may be seen in cases in which the appendix is not at fault. Nevertheless it is in the appendix that it has struck me as most conspicuous. Every surgeon of experience has, moreover, noted instances of fulminating appendicitis, in which when seen early the serous covering was not compromised to any such extent. It is probable that under these circumstances the same necrosis of the mucosa has extended over a more or less wide area inside of the cæcum, and that this is the reason why after the removal of the appendix and temporary improvement, the septic and gangrenous processes continue and cause the death of the patient two or three days later. Such cases as this must continue to be among the opprobria of surgery, unless we open the cæcum and, if this condition be found, resect a sufficient amount of it to eradicate the difficulty.

Since the publication of Dieulafoy's masterly chapter on this subject,[1] it has been established that the appendix becomes troublesome only when its lumen is occluded, and that when it once becomes a closed cavity it is simply a question of the virulence of its contained bacteria whether a small or fatal dose of toxins shall be produced.

Reflecting upon the similarity of acute cases of this character to those of diphtheria, in which beneath an area of membrane the deadly development of germs is going on, the toxins peculiar to this disease being rapidly produced, and not failing to note the beautiful and life-saving virtues of antitoxin as an antidote to the depressing poisons, I have been led to query whether an antitoxin could not be produced which should have a similar effect in cases of acute stercoræmia. While the colon bacillus is not necessarily the sole agent in producing intestinal toxæmia, it is nevertheless known to be that usually at fault. Acting upon this fact, I am now endeavoring to immunize animals to the properties of this organism, in order to see whether their serum may possess virtues by which we may overcome the depression and intestinal paralysis that bring some cases of acute appendicitis to the grave. Researches in this direction are now going on in my laboratory at home. It is quite likely that antistreptococcic serum may have also to be used in these cases.

Cancer.—But the most complex of all problems in surgical pathology to-day, and that upon which we most need light, is with regard to the nature and causes of cancer; and to this topic the remainder of this paper shall be devoted.

The indefinitely sustained power of certain cells to grow and multiply in excess of normal requirements, which is Williams' definition of the essential feature of cancer formation, is common alike to vegetables and animals of any save the simplest type. That cancer appears more prevalent among domestic rather than wild animals is a fact too commonly stated as an evidence of the effect of domestication. Were the same number of wild animals taken at random and carefully examined, I think cancer would be found to be equally prevalent in the wild state. Among animals sarcomata are much more widely diffused than carcinomata, while according to Rayer, carnivorous animals are more prone to cancer than the herbivorous, just the opposite being true in cases of tuberculosis. In the vegetable kingdom it is hard to draw distinctions between various grades of malignancy, yet that tumors kill a large proportion of trees and vegetables will not be disputed by those who have studied the subject. Furthermore, if the method of death be studied, it will be seen to resemble in all essential particulars that which produces ulceration, starvation, and finally death in animals and in man.

Those particularly interested in the general study of cancer—and who is not?—should be promptly referred at once to the various writings of Rodger Williams, who has shown himself a most painstaking and comprehensive student of the subject. To him I gladly acknowledge my indebtedness for much that has been of the greatest value to me, some of which appears in this paper.

Influence of Sex.—According to the statistics collected by him for the twenty-five years previous to 1872, for every 100 males dying of cancer, 229 females perished from the same disease. Of deaths from all causes the proportion among the males was about 1 to 100, among the females 1 to 41. In later years this disproportion has become less marked. Women are still more subject to non-malignant growths. Of cancer in women the breast is involved in 40 per cent., the uterus in 34 per cent., all other parts of the body making up the other 26 per cent. In males the parts about the mouth yield about 40 per cent. of the cases. He collected 1,878 consecutive cases of breast cancer in both sexes, in only 16 of which was the mammary gland in the male involved.

This great discrepancy holds good mainly with regard to carcinoma. When we come to sarcoma, there

[1] Manuel de Path. Int., vol. iii.

is but very little difference between the sexes, all of which Williams interprets as being due to biological peculiarities pertaining to the reproductive and nutritive organs. Thus mammary carcinoma is most prone to arise when post-embryonic developmental activity is greatest.

Influence of Age.—In the evolution of cancer, this can be accurately stated only by comparison of mortality rates with the number of healthy individuals living. After the ages studied are estimated in this way, it appears that the liability to carcinoma increases with each successive decade until the seventy-fifth year. Further study shows that the most characteristic feature in this increase is not mere advance in years, but disproportionate increase in the post-meridian years. By a most instructive diagram Williams shows that the most prolific cancer-producing age is that between the fifty-fifth and sixty-fifth years of life. In other words, during the years when the forces of growth are most active the tendency to carcinoma is small. With the period of tissue and organic maturity begins the liability to the disease, which increases until about the sixtieth year. That the uterus and breast are attacked at an earlier age than other organs is because they have become *passé* with the conclusion of child-bearing life. With the waning of developmental activities the danger of cancer increases, to pass away only when the organs have undergone complete physiological atrophy. The same statement can be made with regard to liability to known infections, whether cancer be an infection or not.

Race, Complexion, etc.—Williams has carefully studied the complexion of three hundred and eighty-four cancer patients, his investigations showing him that, especially among females, there is greater liability to this disease in brunettes than in blondes, and this in spite of the fact that the blonde type prevails among the population generally. He puts the frequency of the disease as being about twice as common in brunettes as in blondes. Beddoe furthermore states that red-haired individuals are even more exempt than others of light complexion. Our own census returns show that cancer is twice as frequent among whites as among blacks; and among whites, in this country at least, and taking it at large, Billings finds that the Irish and German are the most liable.

That the disease is said to be very rare in Iceland, Greenland, Turkey, and Greece, has of course but little interest for us in this country. It is exceedingly prevalent in China; three per cent. of the patients in the Hong-Kong Hospital suffer from the disease. It is said that cancer of the stomach is extremely rare among the Chinese. In India also the disease as a whole is somewhat rare. This may be misleading, however, because most of the people are averse to operations for anything except calculus and cataract. Certainly in the tropics, the world round, the disease is less common than in the temperate zone, though I have often said that we who live in western New York live really in the tropic of cancer, because the disease is so extremely prevalent with us.

Family History.—One of the vexed questions of to-day about cancer concerns its heredity. Williams carefully studied one hundred and thirty-six cases of breast cancer, and discovered a history of disease in the family in one-fourth of the number. So far as I have studied my own case histories, I think my proportion in which there is a family history of this disease to be a little larger even than Williams'. Any such statement as this means a strikingly high proportion of inherited lesion, no matter what this may be. Deformities, defects, and supernumerary organs are not transmitted from parent to offspring in anything like twenty-five per cent. of instances. Moreover, in some cases there is a history of multiple instances in the same family, which have not yet been sufficiently analyzed to yield positive deductions. It must be said that numerous cases occurring within one family, all of whose members live closely together, is fully as much of an argument for the parasitic nature of the disease as is its repeated occurrence in the so-called cancer houses. I know, for instance, of a house in a little town in western New York, in which during three successive generations of inhabitants, deaths from cancer have occurred, these being really among different people of the same family, but not so arranged as to be directly transmitted by inheritance.

If cancer is transmissible by heredity and is not an infection, it should tend to die out in the course of transmission, as do all abnormalites. Thus, out of three hundred marriages in which both husbands and wives were deaf and dumb, in only five per cent. of the cases were the offspring similarly affected; while of three hundred and ten deaf mutes married to those who could hear, the proportion of affected offspring amounted only to one in one hundred and thirty-five (Buxton).

Another element of uncertainty pertains to the fact that cancer is rather a disease of adult life, and it is not yet established whether offspring born before the appearance of the disease inherit any liability to it. Williams reports two instances in which both parents were cancerous, who produced seven children, of whom two died of cancer; also seven marriages in which only one parent was cancerous, from which resulted sixty-two children, of whom ten had the disease. Six marriages between those of whose parents none were cancerous, but in whose families there was a history of cancer, resulted in forty-one children, of whom eight became cancerous.

In this connection it is worth while to remind you of Broca's celebrated report, of the twenty-six descendants of a cancerous patient who attained or exceeded the age of fifty, of whom fifteen died of the disease. It is of interest also to remember that in families returning a cancer history, there will be a disproportionately large number of non-malignant tumors and cysts. Here, too, as in other instances, one generation may totally escape, while the disease appears in the second or even the third. When inherited it appears much oftener in females than in male relatives. Of interest, too, is Williams' conclusion that a large proportion of cancer patients are the surviving members of tuberculous families, and history affords the corollary that no condition which can be inherited better predisposes to cancer than that which also predisposes to tuberculosis. It appears, moreover, that in families in which cancer has prevailed there is a striking evidence of fecundity, the average number of children throughout being 4.6 to a family, while in one hundred and ten cancer families which Williams studied the children averaged 8.8.

The General Health of Cancer Patients.—Cancers appear to prevail largely in those who are subjects of hypernutrition, and this is true even of those who are survivors of tuberculous families, to which there is no exception. Beneke has described cancer patients as having large hearts and arteries with small lungs, which is just the reverse of the condition met with among those predisposed to tuberculous disease. Moreover, nutrition rarely suffers until late, at least among cancer patients, save in those whose alimentary organs are involved.

There is a general belief that a vegetable diet exempts from cancer, as compared with flesh eating; this may possibly be explained by the fact that the majority of a community among whom cancer is relatively rare cannot afford a meat diet, or it may be that a flesh diet actually predisposes to the disease. According to

Beneke, cancers are rare in prisons, where animal food is not freely furnished and where the work is hard. Nevertheless, vegetarians are not exempt from the disease. Indulgence in alcohol, if it has any effect, seems rather protective than otherwise.

Some writers attach great importance to brain exhaustion, wear and tear of the nervous system, due to the habits of society people of the day, as causes of cancer. In spite of Williams' disclaimer, I am induced to think that brain fag certainly does so interfere with nutrition as to have a causative relation to the disease. Moore's view can be pretty generally accepted "that cancer is eminently a disease of persons whose previous life has been healthy, and whose nutritive vigor gives them otherwise a prospect of long life."

Prevalence of Cancer and Its Increase.—In 1840, in England, the proportion of deaths from cancer to the total mortality rate was 1 in 129; in 1880 this had risen to 1 in 28, which shows that in England the death rate from cancer is now about four times greater than fifty years ago. Williams estimates that at least 40,000 persons are now suffering from cancer in England and Wales, whereas in 1840 the number was only about 5,500. Should the disease increase in the future at the same relative rate, it will become one of the commonest of all. This augmented mortality corresponds with increase of population in wealth and improvement in general sanitary conditions. In Ireland, where this happy condition of affairs does not obtain to a corresponding extent, the cancer death rate has been much smaller and has shown no such marked increase. In 1861, in England, there were 376 deaths from cancer to the million of population; twenty-five years later there were 610. During this quarter of a century the number of deaths from phthisis per million has diminished to three-fifths of the number at its commencement.

In the twenty years from 1870 to 1890 the increase in mortality from cancer in England is as follows: In 1870, 384 to the million; in 1880, 468; in 1890, 590. Accepting these published figures from the registrar-general's report, it would appear that the mortality has increased by 53 per cent. Nevertheless, it is not quite so bad as this, because the diagnosis of obscure cases is now more accurate than it was twenty-five years ago.

From a tabulation of the deaths within our own State of New York during ten years, from 1885 to 1895, I find that during this time there have been reported 30,692 deaths from cancer. Doubtless in a few of these cases there may have been a mistake in diagnosis, which will, however, be abundantly atoned for, and more, by the deaths which were really due to cancer and ascribed to some other cause. In 1885 there were 1,882 deaths from this cause; in 1890, 2,878; and in 1895, 3,454. In other words, in the last year of this decade the total number of deaths from cancer was twice that of its first year—which may be interpreted as meaning that the death rate has increased much more rapidly than has the population. During this same decade, also, the number of deaths from all causes has increased only from 80,000 to 121,000. During the last five years of this decade epidemic influenza alone caused 35,000 of the 121,000 deaths. It will therefore be seen how rapidly the cancer death rate is creeping up.

In 1892 Haviland published a monograph, in London, on the "Geographical Description of Heart Disease, Cancer, and Phthisis in England and Wales," in which he maintained that where cancer is most prevalent the country is low and traversed by rivers, which frequently flood the adjoining country; whereas cancer is relatively scarce in mountainous regions or where floods do not occur, and where the subsoil is either hard or absorbent. Thus he found that the Thames runs through a vast cancer field, excepting only where the chalk crops out. Williams, however, states that this cannot be true of all low-lying countries, and seeks to explain the prevalence of the disease in the valley of the Thames by conditions of life peculiar to its population. He calls attention to the fact that cancer mortality is lowest where the struggle for existence is hardest, the population densest, the general mortality highest, the average duration of life shortest, where sanitation is least perfect, and the death rate from tuberculosis highest—in other words, among the working classes—whereas the cancer mortality is greatest among the agricultural community, where people are well-to-do, and where the standard of health is highest and of life easiest. He believes the most potent factors in the causation of cancer to be high feeding and easy living, and that the farmer is in general better off than the city laborer, but more liable to cancer. So, too, in London, where the cancer rate is highest, it is significant that this is particularly true of those parts where the wealthy most abound.

Causes.—When we come to consider more in detail the causes of cancer, we shall have to discard without the slightest hesitation most of the theories which have figured in time past. We shall, in fact, find ourselves narrowed down practically to two. Cells arrange and disport themselves as they do when they form a cancer either in accordance with laws of heredity and atavism, showing ever a tendency to revert to earlier and simpler forms, or else because they are provoked to rebellion by the presence of intruding and extrinsic elements; in other words, we must explain cancer and tumor formation either on the embryonal and evolutionary basis or consider it a parasitic disease.

The traumatic origin of cancer must be based upon stronger evidence than exists to-day if it is to hold good for other than exceptional instances. Undoubtedly men are very much more subject to injury than are women, yet are not half so liable to the disease. Surely men are injured in the thoracic region oftener than are women, yet they suffer from cancer of this region only in proportion of 1 to 115 or 120. If mammary cancer were really caused by injury, the external parts would be certainly more frequently affected, whereas the reverse is true. Cancer for the most part begins as a solitary affection, which would not be the case were it of traumatic origin. If injury be made to figure at all as a cause of cancer, it must be mainly as a cause of sarcoma, since sarcoma can be once in a while traced to such accident. In this consideration I would put epithelioma in a distinct category, since I firmly believe that prolonged irritation of a surface covered by squamous epithelium and frequently infected may produce an epithelioma as an expression of this fact.

That there seems to be, in some cases at least, a particular association between cancer and previous disease of the parts cannot be denied after Volkman's record of two hundred and twenty-three cases, from various sources, of primary cutaneous cancer of the extremities, in eighty-eight per cent. of which he found that there had been pre-existing disease of the part involved; though it must be said that others have not found anything like the same percentage of relationship. At best, then, we can only say that chronic nutritive or infectious lesion cannot necessarily be regarded as antecedents of cancer.

Rindfleisch long ago called attention to what he called the infectiousness of epithelial cells. If it can be shown that he spoke with prophetic accuracy, then the parasitic theory of cancer is established. If, on the other hand, this was but a happy expression showing how epithelial cells react upon each other, then the phrase has no meaning and was simply an allusion to the metastatic spread of cancer.

Certainly the appearances in epithelial cells which have been irritated by coccidia are quite analogous to those presented by cancer cells. The effect of the intracellular growth of coccidia is to produce a hypertrophy, especially of the nuclei, which often assume a volume greater than that of the original cells, only to later completely atrophy. In other words, hypertrophy precedes degeneration. This is true of the majority of cancer cells as well. It is not alone that the parasitic nature of certain bodies found in cancer cells is insisted upon by some and denied by others. It is also true that abnormal cells develop side by side with normal, that nuclei are frequently fused together, that protoplasmic filaments are compressed by cells which have not become keratinized, and that from this series of changes result nests of epidermic pearly bodies whose constitution and appearance are abnormal. This is particularly true when the transformation of young epithelium into horny cells takes place centripetally instead of centrifugally. It is very difficult to explain the appearances brought out by Soudakewitch, who fixed his tissues in osmic acid and colored the coccidia with logwood, or, after fixing by Flemming's solution, found by means of the ordinary aniline stains that they took on a color different from that of the cellular elements.

Two Russian observers, Sawtschenko and Podwyssowski, have done a large amount of work in this direction, which has partly failed of recognition because of its inaccessibility in their language. The former has found that those bodies which he considers to be sporozoa of cancer have no proper membrane, their protoplasm being limited only by the vacuoles in which it is more or less free, it often happening that it is resolved into that of surrounding cancer cells. In its adult form their parasite is regular and rounded, granular in protoplasm, and more dense than that of the neoplastic cells; its nucleus plain, round, with chromatic meshes. This nucleus is decomposed into shreds, as sporulation proceeds, each of which particles becomes surrounded with protoplasm to form a new spore, which in time forsakes the cell in which it has thus been developed, to invade others and spread the lesion. These characteristic appearances should be looked for at the margins of tumors where the tissue is young and the process active, instead of in the central portions where nothing is going on but degeneration. Under the influence of these recent researches of Sawtschenko the parasitic theory, at first considered so seductive and a little later so disappointing, becomes again the subject of renewed interest. By some such theory alone can miliary carcinomatosis be explained.

The common solitariness of cancer invasion in man is frequently emphasized as an argument against the parasitic theory. As the disease has been more carefully studied, it is now universally conceded that cancers may originate by multiple foci, while such conditions as general carcinomatosis and sarcomatosis, corresponding so perfectly to miliary tuberculosis, seem to establish that the disease processes not only disseminate similarly, but both have living agents for their primary causes. Not much comfort for either party can be derived from the fact that multiple and widely different neoplasms may be met with coincidentally. Thus sarcoma and carcinoma may be progressing in the same patient at the same time, while either may be connected with or be independent of syphilitic or tuberculous disease. Nor can anything really reliable be yet learned from a source which, did it exist, would crown all others by its validity, for it must be acknowledged that attempts to inoculate cancer have been abortive in at least ninety-nine per cent. of instances. There is much reason for going over all this ground again, and so far improving upon previous experiments as to transplant tissue from the patient into the nearest possible like tissue of the animal. The old experiments made by Alibert and others were never successful, nor is it known that any surgeon has ever inoculated himself with cancer during an operation. There are but few authentic instances of transmission to the husband from cancer of the uterus. Still about the mouth and perineum, especially where mucous surfaces lie closely in contact with each other, there is much reason to think the disease has been spread from one part to another. Nevertheless, experimental auto-inoculations have almost all failed, in spite of the fact that eroded surfaces do become infected by constant contact with discharge from cancerous sores.

Morau reported, in 1885, the inoculation of fragments from an epithelial cancer of a white mouse into ten other mice of the same kind, with formation of cancerous nodules in eight, which themselves were used for the inoculation of yet other animals, and with success. But he did more than this; he placed healthy mice in cages over a pan containing turpentine and camphor, by which they were kept free from insects and remained in perfect health. In other cages he placed healthy mice along with bedbugs taken from the cages of cancerous mice, and observed that after a few months all the animals infected with these insects were suffering from cancer.

The germ theory of cancer has assumed among certain Italian observers the form of a yeast theory, *i.e.*, it has been ascribed to the presence of blastomycetæ, and organisms of this kind certainly have been cultivated as coming from malignant tumors. Nevertheless, inoculation experiments with them have not yet been completely successful.

In a paper presented before the eleventh congress of Italian surgeons in Rome, October of last year, Roncali summed up our present knowledge with regard to the etiology of cancer briefly as follows:

1. In the cell protoplasm and the connective tissues of cancer are found bodies, not of intrinsic but of extrinsic origin.

2. These are in appearance similar to the coccidia which have been found in the cells of epitheliomata and sarcomata.

3. They are morphologically identical with blastomycetes found in animals which have been inoculated with pure cultures of organized ferments, and resist acids and alkalies as do experimental blastomycetes. They occur only in malignant growths in mankind; in such growths they are found only at the periphery where growth is still active, and not in the centre where degeneration has taken place. They are situated either in the cell protoplasm or between the fibres, rarely in the nuclei. They stain in the ordinary fashion, and can often be obtained from tumors both in man and in animals, and can be grown in pure culture. When these cultivated products are inoculated, they force themselves into the cells and into the fibres, producing the same appearances as in those tumors in which they are naturally found. They moreover show the reaction of cellulose, which is a proof that they are not a degenerative product. Moreover, it is known that certain blastomycetes when inoculated produce hyperplastic rather than inflammatory changes.

Nevertheless, Roncali did not consider the parasitic nature of cancer to be definitely determined. It is of interest to know that Maffuci and Sirleo had found similar bodies and formed conclusions which were in no essential respect different from those of Roncali. They were somewhat inclined, nevertheless, to suspect that the blastomycetes might be present as the result of a secondary infection rather than as a primary causative agent.[1]

[1] Centralblatt für Chirurgie, No. 50, 1896; Centralblt. f. Bakteriol., No. 10, 1897.

Whatever there be to the germ theory of cancer, it meets with this additional difficulty, that it is even to-day almost impossible to state just what tumors should be considered malignant and what not. The adenomata which develop so frequently in the mammæ, the ovaries, the liver, and kidneys, seem to be peculiarly liable to subsequent malignant degeneration, while the frequent recurrence of adenoma of the breast is as well known as its conversion into carcinoma. Whether this conversion is due to infection or not is another thing to be established. The dissemination of adenomatous and papillomatous masses around the inner surface of the peritoneum or along ordinary paths, by way of the lymphatics or vessels, is another feature of malignancy which deserves further investigation. Is this dissemination by implantation, by infection, or by what? Certainly dissemination of normal epithelium is common and is not known to produce cancer. Klebs concludes that an embryonic condition of a part predisposes it to tumor formation, but that the real malignancy of tumors is due to a modification of their cells. The mere presence of cancer cells in a part seems to stimulate the surrounding tissue to growth in an altogether inexplicable way. According to Klebs, the principal change in an epithelial cell which is becoming cancerous is hypermitosis, which itself depends upon hypernutrition. It is characteristic of malignant growths that karyokinesis becomes both exaggerated and irregular, the epithelial cells being fed by the leucocytes, while the membrane of the nucleus becomes thinner, showing the process going on within to better advantage. Characteristic also is it that metamorphosis of the nuclei and formation of new nuclei follow one another in the same cell. Klebs views the cancerous process there as going through the following stages: first, chronic irritation or active inflammation induced by mechanical, chemical, or bacterial agencies; this is followed by the emigration of leucocytes and the progressive development of other cells, which have lost their faculty of normal cell reproduction because of hypermitotic activity. He suggests as a remedy to use inhibiting substances possessed of negative chemiotaxis, by which the leucocytes should be repelled and hypernutrition prevented. He thinks that possibly the toxins of erysipelas have some such power.

Williams makes what at first might seem a strong argument against the parasitic nature of cancer, by showing that in all other infectious lesions, say among the infectious granulomata, there is an identity of structure and arrangement always visible, whereas in cancer of different organs or tissues the widest differences of microscopic appearances are met with. This argument can be offset, however, by another still stronger, to the effect that in true carcinoma, at least, no new cells are introduced, nor new tissues formed, save in the sense of being a reduplication of those already existent. On the other hand, in sarcoma there is an abnormal type of cell met with, which has no business among the healthy cells of the body any more than has a giant cell containing tubercle bacilli. If, therefore, his argument is good in one way, it loses its force in the other direction.

The other side of this question is that which takes no note of parasites, considering the bodies or particles regarded as such by some to be new-cell degenerations or artefacts, or else, if germs, as present only by accident. The evolutionist's view of cancer is not necessarily that of the comparative pathologist, though the latter may hold to the former's notions in this regard. My friend, Dr. Woods Hutchinson, our professor of this department, would summarize it about as follows: The evolutionary view of cancer began unconsciously in the famous theory of Cohnheim's "rests" or "*Schlummer-zellen*"; *i.e.*, little islands or foci of cells, embedded in the adult tissues, which have retained a more primitive or unspecialized character, with its accompanying powers of independent growth. Gradually, however, as the individuality and independence of the component cells of the body became more adequately grasped, pathologists began to realize that it was not necessary to imagine the presence of any undeveloped or embryonic cells, but that any adult cell had the power of relapsing to the primitive condition and initiating the neoplastic process. In fact, cancer, like all other neoplasms and the processes of repair, came to be regarded as a reversion. That individual cells of all descriptions possess reproductive powers is clearly shown by the rapid multiplication of, for instance, the muscular fibres of the uterus during pregnancy, or the heart in hypertrophy, the lymphatics in anæmia, or the connective-tissue corpuscles in the healing of wounds. The reproductive processes from a biologic standpoint may be divided, according to their results, into, first, those in which the product is perfect, the daughter cells in every respect the equals of the parent cells; and, second, those in which this result falls short, the daughter cells being inferior in rank or vitality to the parent cells. Each of these is again divided into two—those whose products are useful to the body as a whole, and those which are not. So that we have four great processes of cell-breeding going on: (1) Those in which the new cells are perfect (true to type) and of utility to the organism, such as genuine hypertrophy, leucocytosis, etc. (2) Those in which the new cells "breed true," but are of no utility to the organism, as the benign tumors. (3) Those in which the new cells are imperfect, but of value to the body, as in scar tissue. (4) Those in which the resulting cells are of lower grade or vitality, and of no utility to the organism, as in sarcoma and carcinoma.

In fact, cancer is regarded as an abortive attempt of gland epithelium to reproduce itself, *i.e.*, a parody upon gland tissue. Its "sin," its essential pathologic character, lies in the fact that its cells breed with an utter disregard of the welfare of the body as a whole. Its danger obtains in that their offspring are so immature and degenerate as sooner or later surely to break down, decay, and poison the lymph current. Sarcoma is a similar process on the part of some mesoblastic tissue cells. Supposing this statement of the nature of cancer growth accepted, can evolutionary pathology offer any explanation for the setting up of this process in any particular group of cells? The evolutionist believes that it can. The one factor which is universally admitted as predisposing to cancer is senility. It is emphatically a disease of middle or old age.

Just as soon as the food supply begins to be cut off from the peripheral organs and tissues, the liability to this process is immensely increased. The same thing will be found to be true of the organs most commonly attacked. In a large majority of cases these will be found to be either functionally senile or ancestrally either in a condition of progressive atrophy or of marked instability. As instances of the first class are the mammary glands and uterus, which after the failure or disappearance of their function become the site of nearly eighty per cent. of all cases of cancer in the female. As an instance in which both predisposing factors coexist, we have the lips and tongue, in which both the atrophic changes consequent upon the loss of the teeth and the "border-line" character of the epithelium, poised between mucous and cutaneous possibilities, as it were, unite to render its cancer record next in darkness. For ancestral instability few localities can compare with the pylorus, the old gizzard region, and here again we have a most frequent site of carcinoma. All of these facts seem dependent upon one common biologic law, and that is that lowered nutri-

tion, whether individual or ancestral, means increased liability to cancerous change; that just as soon as any organ or tissue finds itself being slowly cut off from its nutritive supplies, it is apt to begin breeding on its own account, like plants running to seed in poor soil, in a desperate endeavor to hold their own—in short, that cancer is literally a "rebellion of the cells," as Jonathan Hutchinson has termed it, and, like many another rebellion, is chiefly provoked by starvation and want.

It will be seen, then, that the problem of the nature of cancer and of its cure is a most complex one, and must be studied from many sides. Permit me to indicate in some degree, and yet at present in a purely suggestive way, how we may profitably approach it.

First of all from the statistical side; this must include a careful history of each case, including that of the family. One of the difficulties met right here is that of getting an accurate or reliable family history. The influence of alleged injuries or previous inflammation of the part involved must be carefully weighed. We need to make out especially whether only a cancerous diathesis can be inherited, or only the active disease, or both; for instance, a woman aged forty-five develops a cancer—is her daughter of twenty years of age any more liable than any other girl or not?

We need next to study it by localities, especially those of reasonably fixed proportions, as in the rural districts, in order to know whether it is really or only apparently on the increase. Moreover, it should be established, if possible, whether the numerical increase is due solely to more accurate diagnosis or has an actual basis of reality. The question of so-called cancer houses must be carefully studied, and positive evidence secured. In such instances there must be a careful scrutiny of evidence to show whether this is due to anything more than mere coincidence.

Next we should determine in what race and under what social conditions the disease is most prevalent. This will also necessarily bring up the question of dietetic habits. Is it more prevalent, for instance, among brain workers or other wage earners, among vegetarians or meat eaters?

A study of localities must comprise also an estimation of the physical environment—what the climatic conditions, what the geological formation, what especially the drinking-water supply. Not that this is so important for a single small locality; but if it be shown that where the disease is prevalent similar physical conditions exist, it means a great deal accomplished toward the final explanation for which we seek.

Besides the statistical study of the disease and the external conditions surrounding cancer patients, the problem must also be attacked by a careful laboratory study of fluids and tissues. First, to establish whether the disease is primarily local or systemic. Such a study is, of course, inseparable from the other examinations to be immediately spoken of. Excretions, especially the renal, must be carefully investigated; among other reasons, to ascertain whether the diminution of urea usually noted in these cases is to be regarded as among their causative or consequential features. The blood must be studied with the spectroscope as well as by all the other modern means of examining this fluid. Its hæmoglobin and other physical constituents must be carefully estimated, and its corpuscles frequently examined. The presence of sugar or of peptone in the blood must also be as frequently determined. Then the tissues of the tumor itself must be carefully investigated, chemically, histologically, and bacteriologically. The whole question of inoculability of cancer fragments must be again gone over most carefully, with particular effort to imitate natural and original conditions as nearly as possible. If cancer really be a parasitic disease, it is only a question of time when the parasite may be cultivated in pure culture and inoculated with success. It does not follow necessarily that any of the culture media now in use will suffice for this purpose; to settle this question we must learn how to cultivate sporozoa and all the other reputed parasitic growths outside of the body, and at first without any reference to those whose agency in this direction we suspect.

Finally, the problem must be attacked also from the side of comparative pathology, *i.e.*, from the evolutionist's and embryologist's standpoint. To this effect we must begin with the lower forms of life, and determine the causes which operate to produce neoplasms in them. We must begin even lower down in the vegetable kingdom than those trees which produce tumors (xylomata) as the result of climatic conditions or parasitic vegetables or insects. We must then look upward along the scale, in order to determine whether tumors, including cancers, are entitled to be regarded as reversions to earlier and simpler cell forms, or simpler types of cell arrangement, or whether it can be shown that they never assume malignant characteristics save when provoked thereto by the irritation of parasites.

All of this means not merely a painstaking and almost discouraging task from the outset, but it means more than can be accomplished by any individual working alone. It requires the collective efforts of numerous men versed in all the branches of biological study, and possessed of such training in logic as shall permit of no false deductions; it is, in other words, an enormous task, but not necessarily a hopeless one. If any inquiry into that which affects man's health and welfare deserves to be undertaken by the State or the government at large, it certainly is this. I am far from making light of the studies into which the general government has entered regarding diseases of plants and animals, the establishment of bureaus of animal industry, the detection of trichinosis, etc., by all of which great benefit has accrued to our people generally and the spread of disease been notably limited. Nor would I discourage in any sense the publication of a State's reports concerning the mineralogy, geology, and natural history of its territory, by which knowledge of greatest importance is collected only to be suitably distributed. But I claim that we have in this matter of cancer to deal with a disease of horrible nature, of almost inevitable fatality, of common occurrence, which is certainly on the increase, and that at present we are helpless to combat it as we ought. The people naturally look to us both for explanation and for relief; we do the best we can, but this is often very little. If the lives of our cattle are of value, how much more so the lives of our citizens. In what more humane or, from the merely financial aspect, in what more satisfactory work could a government engage than by the employment of experts competent for this work, endeavoring, no matter how long it may take, to settle this problem? When the real cause or causes of cancer are known and understood, then and not until then can a rational, early, non-operative, and successful treatment be applied.

It would hardly be fair to dismiss this most gloomy and unpromising of all the problems which present themselves to us, without asking, in conclusion, whether any measure, drugs or otherwise, can be regarded as either certain or having any efficacy as against this dread disease? To this, first of all, I would say that in a great majority of cases cancer appears to us as a local affection, which, could it be reached early enough and attacked radically enough, might be extirpated. There is no question but what early and extensive operations in select cases give permanent relief. To bring about this happy result, however, requires the lucky coincidence by which an in-

telligent patient goes early to an intelligent physician, and has his or her trouble recognized at a time when sweeping operation can be made with prospect of success. It requires also that the disease shall be located in some accessible part of the body, in order both that diagnosis may be more exact and operation justifiable —except those trifling growths upon the surface which may be removed by caustic pastes, if one prefer such a course. The treatment by cancer pastes, especially the removal of large masses by this means, is alike unscientific, barbarous, and damnable. It bespeaks the meeting of two cowards—the patient who is afraid of the knife, and the pseudo-surgeon who is afraid to use it. Could the real truth be known about institutions where this method is practised as a specialty, it would be far more discreditable both to intelligence and to the honesty of those who manage them than is generally appreciated.

But what should be said of operations in hopeless cases? I maintain that one has a right, and a duty to the patient as well, to operate in absolutely hopeless cases for either one or more of the four following reasons, providing the patient willingly consent. These are: (1) The relief of pain; (2) the avoidance of constant hemorrhage; (3) the affording of a temporary respite; and (4) the removal of foul sloughing growths, which are an offence alike to patient and family. In cases coming under either one of these heads, the propriety of an operation may be submitted to the judgment of intelligent people, and to the unintelligent the choice of that which one may think well to advise.

A study of the causes of cancer being so inseparable from a discussion of the cell doctrine, one cannot but feel that if there be drugs which influence cell nutrition and cell activity, it is among them that we must look for internal remedies which may have a palliative or curative effect. First among these I place the time-honored remedy arsenic, which, so far as I know, can vie only with one of the latest aspirants to honor, namely, nuclein, for which we shall be ever deeply indebted to Vaughan and his colleagues in the University of Michigan—these being the two remedies which more than any others possess these properties. We certainly lack exact studies demonstrating their power in this direction, but this is another of the investigations to be taken up when this ideal research laboratory, at which I have hinted, is formally organized. It is difficult to say positively whether any true cancer has ever disappeared completely under the influence of either of these remedies. Nevertheless, I have personally seen remarkable retrocession of large and bulky tumors after the use of arsenic internally, and most encouraging reports have of late come from those who have been using nuclein for this purpose. Still it is well known that spontaneous resolution of tumors is believed in by not a few men of greatest eminence, while for myself personally its possibility seems to have been clearly demonstrated in more than one case under my observation. Certain it is, however, that in some instances one must either allow this spontaneous retrocession to have occurred, or ascribe the wonderful change to the influence of certain drugs. For my own part, also, I have such faith in the virtues of arsenic that I prefer to keep all my patients more or less steadily under the influence of the drug in some form for months after operation, while it has seemed to me that I have obtained the best results by using a combination of arsenic, gold, and mercury, in connection with the three haloid elements, chlorine, iodine, and bromine. Whether the benefit which in my observations of this compound has really occurred is due to the influence of one or more of its components upon cell activity, or to the fact that the combination certainly serves as an ideal internal antiseptic, I will not attempt to say. At all events there is more rapid restoration of hæmoglobin, disappearance of the anæmia due to poikilocytosis, as well as of the leucocytosis which is a feature of the cancerous cachexia, than I have known of after using any other drug.

Lastly, without stopping to mention any of the other drugs recently or in time past lauded for this purpose, all of which have so far proved disappointing, I would only mention the modern treatment of cancer by the use of toxins of erysipelas. Having experimented diligently with the toxins and without other effect save to prove their general inefficacy, I am compelled to say that in most respects the treatment has proved a disappointment, the results in most of the cases under my observation having been negative; while for every instance in which more or less benefit has resulted, I could bring two or three to bear in which positive injury has resulted. It may be, however, that we are on the right track in this matter or near it, and need mainly to enlarge our observation and still further use our reason.

CLINICAL REMARKS ON SOME SUPPURATIONS OF THE URINARY APPARATUS.

By REGINALD HARRISON, F.R.C.S.,

PRESIDENT OF THE MEDICAL SOCIETY OF LONDON.

I HAVE selected for consideration some points which seem to arise out of the pathology of certain suppurative processes as observed in the urinary organs in relation to the more modern treatment of surgical lesions and infections as generally practised.

I shall first illustrate my observations by taking the most common as well as the farthest-reaching cause of suppurations of the urinary organs, as occurring in the form of primary gonorrhœal infections in the male and the female, and as secondary developments in other parts of the genito-urinary system, as more frequently observed in the latter sex.

The advances that have been made in connection with the bacteriology of the urinary organs, in reference more particularly to the kind and extent of these infections, has already led to some useful applications in the way of treatment, which I will briefly notice. The investigations of Guyon, Janet, Hallé, and others of the French school, more particularly as regards the life history and cultivation of these micro-organisms, are of much interest and importance. It is, however, to the practical aspect of the subject that I shall confine my remarks.

The first point that strikes one is that many of the cases spoken of as instances of chronic suppurative urethritis or gleet represent a far more extensive invasion than is generally supposed to be the case. In this lies, I have no doubt, an explanation of the difficulty that is not unfrequently experienced in bringing cases of this kind to a successful and speedy termination. Many gleets are merely reinfections of the urethra from a bladder which serves the purpose of a medium for bacterial cultivation. So long as a gonorrhœa is confined to the area of the urethra, as defined by that portion of the canal which lies in front of the compressor urethræ or "cut-off" muscle, the task of successfully combating the infecting suppuration is not usually a difficult one. The disease is within limits which can be readily acted upon by various agencies, administered either locally or by internal medication, and its course is generally limited both in severity and duration. When, however, these boundaries are exceeded and the bladder is invaded, it is not easy to prevent reinfection taking place as if from an extraneous source. Hence the disease may be almost indefinitely protracted.

Nor is invasion of the bladder in this way uncommon or necessarily indicated by acute symptoms, such as would unmistakably draw attention to the occurrence. In most instances of this the prostate is the only part of the urinary apparatus that shows any active indication of contact with the septic products, the mucous membrane of the bladder, though harboring them, being singularly insensitive to bacterial influences. That infection occurs in this way, may be readily demonstrated. When the bladder has been thus infected, the conditions of the urinary organs, particularly during the night, are extremely favorable for bacterial cultivations, a circumstance which I believe may explain the constancy and degree of matutinal suppuration exuded by the urethra, which is a prominent symptom in this class of cases.

It is rare, I believe, for gonorrhœal organisms to make their way up the ureters and to invade the kidneys, a fact which is no doubt due to the guarded manner in which these ducts enter the bladder and the constancy of the downward flow of the urine. That renal infection and urethral inflammation, sufficient to cause a pyelitis of the former and a contraction or stricture of the latter, can occur has been demonstrated as possible. Some years ago I examined the body of a middle-aged man who died from acute single pyelitis rapidly following upon a first attack of gonorrhœa. The ureter of the kidney involved was extremely dilated, a circumstance which was believed to be due to the patient having been in the habit for some years previously of passing renal calculi. The opposite kidney was much congested. Mr. W G. Nash[1] has recorded a case of strictured ureter which was probably caused in this way. In the female the widespread effects of the gonorrhœal infection are very generally recognized.

The suspicion, however, that the bladder may be infected with micro-organisms should be made a matter of proof, and this can generally be done. For this purpose care should be taken to obtain a specimen of the urine as it exists in the bladder, minus any contaminations it may pick up in its transit along the urethra. The first portion of the urine passed should be rejected as probably containing the flushings of the canal, the balance being separately collected as representing the constituents of what may be called vesical urine. When it is possible a catheter specimen should be obtained in accordance with the directions of the Clinical Research Association, if there are reasons for believing that the bladder is infected. In this way gonococci may be detected in vesical urine in cases of gonorrhœa.

The mere fact that the urine is shown to contain bacteria does not necessarily imply that the individual is capable of inoculating another with gonorrhœa. When, however, the gonococcus is discovered in the urine or the discharges of the patient, as is not unfrequently the case, I do not think there can be any doubt as to the possibility of its transference to some one else. The bacteriological examination of these secretions may furnish important evidence in determining whether a person who has been comparatively recently infected should be allowed to marry. So long as these conveyors of infection can be detected in the urine or the discharges, so long may we expect that transference of the disease is apt to follow.

In these cases of secondary infection of the bladder caused by extension from the urethra, I have for some time placed much reliance upon the irrigation of the bladder and urethra with antiseptics as described by Dr. Janet,[2] with some modifications. The object is attained in the following manner: My apparatus consists of an ordinary hydrostatic bladder tank, holding about one pint of water and fitted with a nozzle to which a No. 8 Jacques rubber catheter is attached. The tank is elevated about six feet from the ground, and is filled with warm water containing thirty minims of Condy's fluid to a pint of the latter. For lubricating the catheter I use carbolized vaseline.

The patient, having emptied his bladder spontaneously, is placed in the recumbent position and the catheter is then passed. Before the nozzle of the irrigator is connected with the catheter as it lies in the bladder, the fluid is allowed to run off for a few seconds so as to insure that there is no free air in the tube of the apparatus. Then the connection is made and the fluid is allowed to flow into the bladder by degrees, until the patient is conscious of feeling distention. I generally use from twelve to sixteen ounces for this purpose, allowing it to enter the bladder in jets of about three or four ounces at a time. In this way the feeling of any sudden or extreme fulness is avoided and the entire area of the mucous membrane of the bladder is unfolded and opened out and thus comes in contact with the permanganate solution. When a sufficient degree of bladder distention is obtained the catheter is slowly removed, care being taken not to allow the fluid to escape. I then usually lightly palpate the bladder above the pubes with the hand before the patient stands up. This he should then do and proceed to empty his bladder of its contents by his natural efforts. Thus not only is the bladder washed out but the whole urethra is flushed in a manner that is impossible with any other artificial method. As the patient is voiding the contents of his bladder it is well to direct him suddenly to interrupt the outflow once or twice by pressure with the finger on the penile urethra. In this way the lacunæ of the canal are also distended and flushed by the irrigating fluid. This completes the process, which may be repeated once or twice in the twenty-four hours, until the urine and the urethral mucus are found free from organisms. Most patients after proper instruction will be able to carry out all these details. On the conclusion of each irrigation the patient should rest for a time in the recumbent position.

I have referred only to the permanganate of potassium in great dilution as the flushing agent for use in these cases. Half a drachm of Condy's solution, as I have already mentioned, gradually increased to a drachm in a pint of water, has given me good results. Neutral sulphate of quinine (one grain to the ounce) may also be used. More rarely I have employed nitrate of silver (one-sixteenth of a grain to the ounce), and perchloride of mercury. The last sometimes produces a good deal of pain even when it is used only in the proportion of one in ten thousand. I have no doubt that for aborting infections the perchloride is the most effective. When used for the latter purpose in the proportion of one in ten thousand, and after the solution has been spontaneously voided from the bladder, as in the act of micturition, the bladder may be refilled with a strained solution of albumin, say, that yielded by one fresh egg, in a pint of tepid or nearly cold water. If this is done and the albuminoid solution voided from the bladder, any pain, smarting, or spasm that the perchloride solution produced at once ceases. Similarly a weak solution of chloride of sodium injected into the bladder after a solution of nitrate of silver has been used for this purpose, not only removes any irritation the latter may provoke but coats over the inflamed mucous membranes with a thin layer of chloride of silver which often affords much relief when cystitis is present. Probably there is no better bactericide than nitrate of silver in these cases, but it requires to be used with the precautions I have mentioned, when good results may be obtained.

[1] Brit. Med. Jour., April 8, 1893.
[2] Jour. des Malad. Gén.-Urin., Paris, 1896.

In this class of cases, in which suppuration proceeds directly from infection, the internal administration of bactericides may be advantageously combined with the local treatment I have just referred to. In rendering the urine not only sterile and destructive to the life of the gonococcus there are no more effectual agencies than some of those which are derived from the vegetable kingdom. I refer more particularly to those volatile oils which are so largely eliminated by the kidneys, among which I may instance sandalwood, copaiba, cubebs, and other similar drugs. By these it is possible so to saturate the urine as to render the existence of certain forms of infecting bacteria impossible. I shall, however, later on refer to other methods employed for sterilizing the urine, which may also be utilized in connection with the treatment of infecting forms of urethritis and cystitis.

I will now proceed to notice other forms of urinary suppurations, which may be best illustrated by certain cases of prostatic obstruction. Though the urine is in these instances usually purulent and charged with bacteria, the latter are not infective in the same sense as those I have previously referred to in connection with a specific form of urinary suppuration. On the other hand it must be remembered that these microorganisms are readily capable of transference from one individual to another through the medium of catheters and instruments of this kind, and thus they may be regarded as the factors in the causation of very extensive and far reaching suppurations in these parts.

The principles of treatment in this class of suppurations are the same as those I have already referred to, subject to certain modifications which I will proceed to notice. Putting aside the consideration of the precise means which these cases often require for mechanically emptying the bladder and thus preventing decomposition of the urine taking place, the restoration of the secretion to its normal state will be mainly brought about by the employment of antiseptics in the manner indicated. The more or less atonic condition of the bladder in these obstructive cases seldom permits us to employ the process of auto-irrigation as previously described, and we must therefore for this purpose avail ourselves of one or other of the methods usually practised.

In offering a few remarks on the toilette of the bladder I will do so in reference (1) to the disposition of the parts requiring ablution, (2) to the mechanism employed, and (3) to the composition of the cleansing fluid. Most of us, I think, will admit that we are disposed to draw our ideas relative to the process of washing out the bladder from the natural state of the parts, such as we see in anatomical plates. If, however, we take for our guidance the majority of pathological specimens illustrating the obstructive diseases of these parts, we shall at once recognize the difficulties that beset us in our endeavor to wash out these examples, as we should do in the case of a pint pitcher. Take, for instance, the hypertrophied bladders with their various saccules, pouches, and dependencies which are met with in connection with advanced urethral stricture in younger adults and in persons of more advanced age who are the subjects of obstructive prostatic disease. In many of these the bladder is no more like the natural organ than the interior of a glass bowl resembles the section of a coarse bath sponge. The contents of the latter one could hardly ever hope to wash out effectually, though one might succeed in soaking them out. For washing out the bladder I almost invariably employ the hydrostatic tank which is now so generally used. It has, I believe, many advantages over syringes, which I need not here stop to enumerate. When the bladder is much fasciculated washing out should be done in the recumbent position, with the object of opening out the mucous membrane as completely as possible without causing pain, the object being to reach irregularities on the surface which otherwise would escape contact with the lotion. When the bladder is much pouched it is a good plan after filling it and before removing the fluid to cause the patient to agitate his body from side to side so as to bring any dependencies there may be within reach of the antiseptic. In various ways such as I have indicated the process of washing out the bladder may be rendered more searching.

For washing out in ordinary cases of bacterial urine I usually prefer boric acid or the boroglyceride. Condy's fluid or iodoform may also be similarly employed. As I have already said, a solution of nitrate of silver, in the proportion of one-twelfth of a grain to the ounce, is often efficacious in rendering turbid urine clear after other things have failed.

The sterilization of the urine by internal medicines is an important adjunct in the treatment of the class of cases I am now referring to. It is quite unnecessary to draw your attention to the many obvious ways in which the urine may thus be influenced. The specific gravity, the reaction, and the composition of this secretion may to a large extent be artificially influenced, and in these directions the course of suppurative diseases of the urine passages may be most importantly and favorably acted upon.

And this brings me to speak of some of the means at our disposal for rendering the urine sterile, so far as the most important factors in suppurative diseases are concerned. I have already referred to the sterilizing influence that certain oils and essences, such as sandalwood and copaiba, are capable of exercising in this way. No less marked is the effect that boric acid taken internally is capable of effecting in controlling bacterial life in the urine. Probably no better proof of this exists than in the results observed in connection with operations on the urethra, such as the passing of catheters and in internal urethrotomy. The late Dr. Palmer, of Louisville, showed many years ago that by the use of boric acid beforehand the development of urethral rigors and fever under these circumstances was rendered highly improbable, and this has since been most amply proved to be the case. Similarly the use of quinine as a prophylactic against urine fever has been shown to be most efficacious: salol and other like drugs are also well recognized as urine sterilizers.

Though boric acid, in doses of ten or fifteen grains three or four times in the day, is probably one of the most reliable sterilizers, it so often disagrees and causes dyspepsia as to interfere greatly with its use for this purpose. Some years ago my attention was called to a preparation called boro-citrate of magnesium, which was described by Dr. Kockler, of Kosten[1] in Germany, as a solvent for uric-acid calculi and gravel. In the communication referred to it is stated that it is prepared by dissolving boracite in citric acid, boracite being a natural borate of magnesium which is found in Strassfurt. Whether it is actually a solvent for uric acid I am not prepared to say. While testing it for this purpose I found that it frequently had a remarkable effect in sterilizing and clearing up purulent urine and in favoring the expulsion of calculi and gravel, by its flushing effects on the urine passages. For the latter purpose I have used it for the last ten years with considerable effect in conjunction with other means for preventing urine decomposition. This is a specimen as prepared by Messrs. Bell & Co., which I am in the habit of prescribing in teaspoonful doses in half a tumbler or so of either warm or cold water two or three times in the day. It is extremely palatable to take and readily dissolves.

There are other means for sterilizing the urine by

[1] Berlin. klin. Wochen., November 3, 1870.

the mouth which I will mention, as one method or one drug is not universally applicable. There is a combination of the salicylate of sodium with the benzoate of sodium which often possesses this power in a marked degree. "I have frequently found urine which has been rendered opaque by the presence of pus and was swarming with bacteria to be rendered clear in the course of a few days by this preparation. I usually prescribe fifteen grains of both of these salts to be taken together three times a day in an ounce of chloroform water. The hyposulphite of sodium in half-drachm doses has also in some instances effected the same object.

The principle of urine sterilization may, however, be extended to other purulent or bacterial conditions of the urinary apparatus. I refer more particularly to some of those chronic suppurations resulting from the formation of abscesses in connection with the prostate and prostatic urethra, in which the pus was originally discharged, sometimes against gravity, into the latter canal. These are often most difficult to heal by reason of the absence of a free and dependent opening. Yet, on the other hand, the opening of the perineum and the incising of the prostate to secure free drainage of the discharge is a proceeding that cannot always be undertaken without some degree of risk in elderly subjects. The thorough cleansing of these deep parts by the use of antiseptics in the form of auto-irrigation, as described in the earlier part of this paper, will be found efficacious in many of these cases of chronic suppuration. In some instances of prostatic suppuration it is almost impossible to flush a sinus connected with this part so long as a catheter of any kind is retained in the bladder; on the other hand this object may be often readily effected by the spontaneous contraction of a more or less distended bladder. In the sinuses arising out of tuberculous prostatitis this method often proves very effectual.

Again I have resorted to this method of flushing urinary fistulæ with some antiseptic fluid when the primary cause of them has been removed, as by gradual dilatation or after internal urethrotomy. Tortuous routes through the perineum may, by flushing through the medium of the bladder two or three times if necessary in the twenty-four hours, be thus healed.

A few months ago I saw a middle-aged man with a tight stricture in the deep urethra which admitted only a No. 4 bougie. In addition there were two chronic perineal fistulæ, one opening in the left buttock and the other by the side of the scrotum, through which almost the whole of the urine was passed at the time of micturition. The patient's condition was an extremely distressing one, as it was impossible for him to pass his urine with any degree of comfort except upon a watercloset. I divided the stricture from within by Maissoneuve's urethrotome. A catheter was then tied in the bladder for forty-eight hours, and on its removal a No. 12 silk catheter *à boule* was introduced morning and evening. After being washed out by means of this in the ordinary way, the bladder was filled with over half a pint of warm boric lotion, which the patient was required to void naturally in the standing position on the catheter being withdrawn. The fluid escaped as in the ordinary act of micturition with this patient, namely, partly by the urethra, and partly through the false routes. The proportion of the fluid coming through the urethra gradually increased, while that passing through the two fistulæ grew less daily, and in the course of ten days entirely ceased. This method of procedure I have found from repeated trials to contribute importantly in promoting the sound healing of these fistulæ, and the comfort and cleanliness of the patient.

THE TREATMENT OF FOLLICULAR ABSCESS OF THE FOSSA NAVICULARIS WITH ATTENDANT FISTULA.[1]

By CHARLES H. CHETWOOD, M.D.,

LECTURER IN OPERATIVE SURGERY AND IN GENITO-URINARY DISEASES AND SYPHILIS AT THE NEW YORK POLYCLINIC MEDICAL SCHOOL.

The condition described in the title of this paper is not an infrequent one, and, unless my own experience is peculiar, is generally obstinate to treatment, especially when the accompanying fistula is complete with both internal and external openings.

I have for the past year or so depended upon a method of procedure in the treatment of these cases which has of late developed into a routine so successful in its results as to warrant a detailed description for the benefit of those whose experience has not taught them a better method.

In order to cover all the cases I have treated which came under the above heading, I divide them into three classes, of which I report a successful case representing each class:

I. Follicular abscess with blind internal opening.
II. Follicular abscess with blind external opening.
III. Follicular abscess with complete fistula.

The etiology of all of these varieties is the same, there being an extension of inflammation during an

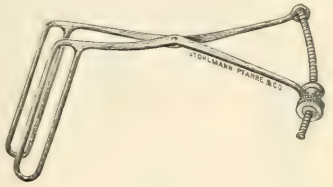

Fig. 1.

attack of acute or chronic urethritis resulting in periurethral abscess, which leaves a permanent fistulous tract of one of the above-named varieties connecting with a distended follicular sac of varying dimensions. The first is probably the most frequently met with, and consists simply of a small pouch behind the meatus, connected with the urethra by a dilated follicle mouth. The second is when the natural follicular opening becomes closed and the abscess finds vent externally. The third is when a complete urethral fistula exists with both external and internal opening, often the result of an unwise external incision. Internally the mouth of more than one follicle may connect with the sac and externally the abscess may open on both sides of the frenum.

The symptoms accompanying these conditions are those resulting from a contracted meatus. There is more or less induration at the site of the fossa navicularis and a certain amount of purulent urethral discharge from the meatus when there is an internal opening, or alongside of the frenum when an external opening exists, notably when pressure is made over the swelling.

As regards diagnosis, the existence of periurethral abscess is self-evident. The nature of the fistula is determined by the injection of a small quantity of peroxide of hydrogen into the vent of the abscess, which will find its way to the end of the tract, and demonstrate whether it be a blind or complete fistula. For examination I employ a simple wire urethral speculum, as shown in the accompanying illustration (Fig. 1). The position of the speculum introduced, demonstrated in the next illustration, is particularly useful, the object being to make the floor of the urethra pass over the end of the speculum beneath the index

[1] Read before the New York County Medical Association.

finger, which gives a much better field of vision than when held in the ordinary manner, and is utilized in the later part of the treatment hereinafter described (Fig. 2). I have found sunlight entirely efficient, although reflected and artificial light may be employed if preferred.

In regard to what is generally held to be the prognosis in these cases, I quote from Morrow's "System of Genito-Urinary Diseases," which states "they are frequently obstinate. Some of the smallest resist all those means of treatment so long as only the trivial operations of stimulation and catheterization are resorted to"—implying that more definite surgical interference is recommended.

Such rational treatment of these cases generally referred to in the books is incision of the swelling (externally or internally), keeping the cavity packed until healed, and, when a complete fistula exists, denudation of the whole tract by dissection or scraping, followed by careful suturing. I have found, however, and others have found the same, that such treatment is not always practicable, and certainly not invariably

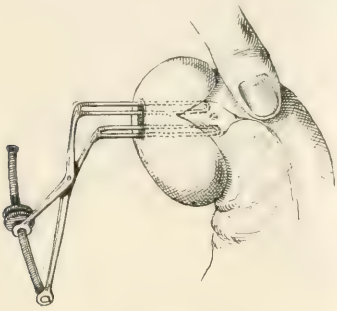

Fig. 2.

the means of effecting a cure. If the incision is made internally, it is difficult subsequently to keep the cavity properly packed in the interior, and thus a failure may result; and if an external incision is made the danger of making a complete fistula is presented. Fissures which are demonstrated to have an internal opening only are the most favorable for this mode of treatment; but even then the follicular mouth within the urethra may be only temporarily occluded, and if it reopens during the treatment after external incision the danger of complete permanent urethral fistula is again threatened. I do not doubt that many successful cases under various other means of treatment might be reported, but the obstinacy of the generality of cases remains; hence I do not hesitate to recommend the course of treatment I have adopted in all cases of the varieties already named, and at my hands it has never yet failed of a cure.

The method of applying this treatment is as follows: The patient is placed in the recumbent position, in a good light, and a wire speculum is introduced into the urethra, as the treatment is always applied from the interior whether or not there be an external opening. Prior to the introduction of the speculum, a small quantity of four-per-cent. solution of cocaine (or eucaine) may be injected into the urethra and retained three minutes, after which a few drops of the same solution are injected through a hypodermic needle into the several parts underlying the fossa navicularis and thus absolute local anæsthesia is obtained. Such complete anæsthesia is only resorted to at the first sitting, when an incision is generally required and more thorough inspection of the interior is desired. Proper inspection is facilitated by conforming to the position above illustrated (Fig. 2). A fistulous orifice is readily recognized when brought beneath the end of the speculum.

The subsequent treatment is practically the same whether the fistula be complete or incomplete and whether the opening be internal or external. An incision is first made interiorly over the site of the

Fig. 3.

periurethral swelling, unless there is an accumulation within the sac and there already exists a large enough opening to admit the introduction of the nozzle of a pipette. The urethra is now packed with absorbent cotton from the lower end of the speculum up to the point of the incision, and now with a specially constructed pipette (Figs. 3 and 4) a few drops of the twenty-five-per-cent. solution of peroxide of hydrogen are injected into the interior of the sac, which requires the adoption of the second position. Effervesence now takes place freely, and the overflow is caught in the absorbent cotton, after which the speculum is closed and withdrawn with the cotton in its grasp. This completes the first treatment and the patient is told to return in two or three days, being apprised of a probable free purulent discharge as a result of this first application, for which a mild injection may be given.

The next application is more trivial and may be performed with or without cocaine, according to the sensitiveness of the urethra. A small quantity of the same solution is introduced in the manner already described and subsequently continued applications are repeated at about the same intervals.

The effect of these applications is to cause rapid contraction of the sac and destruction of its pyogenic properties. When the stage is reached where the discharge has practically ceased and a small blind internal fistula is all that remains, position No. 1 is resorted to, and the solution is applied to the fistulous opening by means of a fine glass rod, which procedure should in a short time effect a complete cure. I find it advisable toward the end of the treatment to substitute the five-per-cent. for the twenty-five-per-cent. solution when a less destructive action is necessary than in the early stage and there is adventitious tissue to be removed by the caustic action of the stronger solution.

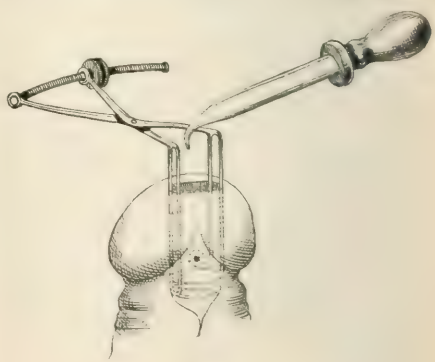

Fig. 4.

The length of time necessary to keep up this treatment varies from two to six or eight weeks, according to the severity of the case. The intervals between the treatments are from two to four days, according to the irritation produced. The most obstinate cases are those in which complete fistula exists and those in which there

is underlying tuberculous diathesis. All cases should result in a cure when the treatment is properly performed.

The preparation employed in the treatment is manufactured under the proprietary name of pyrozone, and the so-called caustic and antiseptic preparations of this substance are nothing more nor less than twenty-five-per-cent. and five-per-cent. ethereal solutions of peroxide of hydrogen, and are referred to as such in this article. This compound was formerly known and manufactured under the name of ozonic ether some twenty-five years ago. It is unnecessary to mention here the facility with which peroxide of hydrogen covers the whole surface of pus-forming cavities, exerting an active penetrating antiseptic influence. The peroxide of hydrogen preparations generally sold are aqueous solutions of this substance. The ethereal are more active and the above percentages of peroxide of hydrogen are greater than those contained in any of the aqueous preparations manufactured. The ether also is a desirable ingredient, being a solvent of fatty matter, which may readily obstruct the proper action of any antiseptic application on diseased surfaces.

The pipette I make myself out of an ordinary medicine dropper with a long nozzle, which is shaped in the flame of a Bunson burner so as to turn at a right angle and then drawn to an extremely fine point; otherwise the solution, being ethereal, cannot be retained.

The following classified cases demonstrate the effectiveness of this mode of treatment:

Case I. represents Class I., viz., follicular abscess with blind internal fistula. June 9, 1894, Mr. C. L—— had had four attacks of acute urethritis. The latter one, of over two weeks' duration, was complicated by a phlegmon commencing behind the frenum, which had been opened by the physician who was then treating him. When he was first seen by me, there was an internal fistula connecting with a small abscess, which was discharging itself into the urethra, and at this time and for several days later the danger of a complete fistula forming was threatened by spontaneous external opening. A probe introduced from within could be felt just beneath the mucous lining of the prepuce, on both sides of the frenum, which was so thin that the probe could almost be seen. After one week of the above treatment the danger of external opening no longer presented, and at the end of two weeks the abscess had stopped discharging and the fistula closed soon afterward.

Case II., an example of Class II., follicular abscess with blind external fistula. Mr. J. P—— had an acute urethritis of two or three weeks' duration, some time during which a follicular abscess had formed at the fossa navicularis, unnoticed by the patient, but had opened spontaneously externally. July 18, 1894, an internal incision was made and the usual treatment carried out, with the result of complete recovery in three weeks.

Case III., Mr. H. F. G——, was one in which a complete fistula was formed. The patient had large swollen glands on both sides of the neck, was anæmic and had an extremely irritable bladder, very obstinate to treatment, suggesting the possibility of a tuberculous element. There was an indurated sac behind the meatus, an external opening on the right side of the frenum, and an internal one on the floor of the meatus, so that peroxide of hydrogen injected through the external opening would effervesce through the meatus. On account of the patient's general condition and the urgency of his bladder symptoms, the trouble near the meatus was not immediately treated, except to wash it out occasionally with different antiseptic solutions, which produced no curative effect. After the patient had been under treatment for four or five months, his bladder trouble had almost entirely subsided and his general health was much improved, but the fistulous openings near the meatus persisted, and after remaining away two or three months longer he returned to be treated for this condition. January 21, 1896, I enlarged the internal opening and followed up the regular course of treatment as if no external opening existed. The patient was under treatment for about seven or eight weeks, when the indurated area had contracted down to almost nothing and both fistulous openings had entirely closed, it being impossible to press out any discharge internally or externally.

In conclusion, I would state I have seen all of the above cases at periods of from three months to a year after the cessation of treatment, and in none was there any sign to indicate that the recovery was not permanent.

COW'S MILK IN INFANT FEEDING.

BY WALTER G. MURPHY, M.D.

EAST HARTFORD, CONN.

The first year of childhood, often for purposes of study arbitrarily named the first nutrient period, presents to the student of medicine many complex, interesting, and important problems. To us as physicians is intrusted the important office of guiding the growth of the child as it passes through its developmental stages, that in its growth it may retain or acquire the priceless boon given mankind, namely, good health. As a factor in the growth and general well-being of the child, food occupies a most important position, and it seems appropriate at this time to present for your consideration the subject of cow's milk in infant feeding. The writer cannot hope to present an exhaustive treatise on such an extensive and varied topic, but rather to touch upon a few of the many difficulties with which we have to contend.

All authors agree that cow's milk, which is now universally accepted as the best substitute for maternal milk, must be modified to resemble more closely nature's product. A comparison of the analyses of cow's milk and woman's milk will demonstrate the difficulties to be overcome in arranging a diet of cow's milk for a young child. Leed's analyses give 4.01 fat and 2.06 albuminoids in woman's milk, and 3.75 fat and 3.42 albuminoids in cow's milk. Other observers give even a higher percentage of albuminoids in cow's milk.

The difficulty, outside of the laboratory, is to dilute the proteids and still retain the fats at a proper standard compared with woman's milk. The acid reaction of cow's milk also presents difficulties. Woman's milk is almost uniformly alkaline. If not, it should not be used (Rotch). Cow's milk, as usually received twenty-four hours after milking, is quite acid, and I believe just as much is due to this fact as to the proportion of proteids present. Milk, as drawn from the breast by the child, is sterile. The nicety of mechanism of the breast in performing its function allows no possibility of fermentation before the milk enters the infant's mouth, and as the gland collapses as it is gradually emptied a vacuum is avoided. If, however, milk is exposed to the air, bacteria multiply very rapidly by the hundreds and thousands, and in time, shorter in summer than in winter, increase to such proportions that fermentation occurs, lactic and butyric acids are formed, and the milk sours. Milk twenty-four hours old is an entirely different substance than when perfectly fresh. Originally not harmful, as at-

[1] Read at the semi-annual meeting of the Hartford County Medical Association, Hartford, Conn., April 21, 1897.

tested in some countries where children are nursed directly from the cow, milk becomes by natural changes, if allowed to occur, a rank poison.

It has been found by experiment that if milk, immediately after being drawn from the cow, is cooled to 40° F., all bacteria growth is at once arrested and remains so if the milk be kept at a low temperature. With our present manner of handling milk in the dairy, unless absolute cleanliness is observed about the barn, cow, and hands and clothing of the milker, it is impossible to get a thoroughly sterile milk. Some microbes develop very rapidly, doubling in twenty minutes, while others require a longer time. But that cooling rapidly is effective is fully proven by an experiment at the Yale Agricultural Experiment Station. Two cultures were made on gelatin plates—one of milk cooled to 40° F., and the other perfectly natural milk, with all its gases and animal heat retained. The first plate, after sufficient exposure, gave only twelve colonies, while the second contained thousands.

In experiments to determine the size of the curd of cow's milk as compared with the curd of woman's milk, it is noticed that the precipitate obtained by the addition of acid to cow's milk is tough and hard, while the curd of woman's milk is soft and flocculent and of smaller size than cow's milk. I believe this great difference is due principally to the fact that there is an acid fermentation in cow's milk, due to the presence of bacteria which we do not find in woman's milk. The curd is by comparison larger in cow's milk than in woman's milk, but it does not seem possible that in its normal state, as received by the young animal, it would precipitate in the tough, hard mass seen when acid is added in a test tube.

To determine this fact, I undertook a series of experiments, and in every case it was noticed that the curd was smallest when the milk had not undergone an acid fermentation. Hydrochloric acid was added to the milk, first in a weak solution gradually, and then to a similar specimen of milk pure acid was added quickly:

No. 1.—Milk, 4 drams; water, 8 drams—representing the quantity for a child two or three weeks old. Slightly acid. Heated to 100° F. On adding acid the curd was precipitated in fine flakes.

No. 2.—Whole milk, acid. Treated in the same manner, precipitated in tough, hard masses, as when milk has soured in summer.

No. 3.—Same quantity of milk and water. Treated with a weak solution of hydrochloric acid, 0.02 per cent., as represented in normal gastric juice (Schmidt). Acid added slowly and curd fine, as in No. 1.

No. 4.—Whole milk with weak solution of acid added slowly; precipitated in small particles suspended in the milk. On separating the fluid from the curd and comparing the precipitates, it was noticed that while No. 4 gave more in quantity, the curd was composed of soft, easily broken bodies, about the size of those obtained in No. 1.

No. 5.—Pasteurized milk, diluted one-quarter and heated to 100° F. Slightly acid. Diluted and tested with strong acid; curd finer than in experiments 1, 2, 3, and 4.

No. 6.—Whole milk, with strong acid, required twice the quantity of acid used in No. 2, and the curd was finer than in experiments 1 and 2.

No. 7.—Milk diluted one-quarter. With dilute acid added slowly, the curd finest of all specimens so far examined.

No. 8.—Whole milk tested with dilute acid. Curd finer than in experiments 1 and 2. Pasteurized milk, tested with strong acid, does not give the tough curd noticed in whole raw milk. The curd resembles more that obtained in diluting ordinary milk. Aerated milk, tested eight hours after being received from delivery wagon, is very slightly acid.

No. 9.—Milk diluted one-quarter. Temperature, 100° F. Tested only with full-strength acid. Required more acid to cause precipitate than any diluted specimen examined. Curd very fine, resembling human-milk curd.

No. 10.—Whole milk, with strong acid, precipitated a curd as fine as any diluted specimen except No. 9. Required four times the quantity of acid to precipitate as did ordinary morning's milk received at the home about the same time.

Lehman has noticed that when woman's milk is tested after standing some time the curd is heavier and more solid than when precipitated immediately after being drawn from the breast. Cow's milk twenty-four hours old will react to less acid and more quickly than new milk. Milk curdles more quickly and the curd is heavier when acid is added quickly than when the same quantity of acid is added gradually.

Applying these facts to the action of the gastric juice in a child's stomach, I think we are justified in believing a similar precipitate would occur. A milk which has undergone a partial acid fermentation, and is of a decidedly acid reaction, coming in contact with the acid of the stomach, we should expect a tough precipitate, as noticed in the test tube; whereas a perfectly fresh milk, not containing an excess of acid, or a diluted milk when the acid is also diluted, would precipitate a finer and softer curd than would experiment 2.

While we cannot compare absolutely a chemical action in a test tube with the action of the normal secretions in the stomach, I believe it is evident that an excess of acid—that is, the acid of the milk plus the acid secretions—would produce a different chemical action than if the gradually secreted gastric juice alone caused the precipitate (Dalton).

From these experiments, then, it would seem that when measures have been employed to lessen the fermentation of milk the curd is entirely different from that of ordinary milk as obtained from the cart, and, further, it will be noticed that when the milk has been aerated immediately after milking, the curd is finer than that of Pasteurized milk, with which the effort is made to check fermentation after it has already begun.

Babies, as a rule, are able to digest a stronger milk in winter, when there are fewer germs, than in summer, and a case seen during the past season illustrates that fact. A baby, six months old, was taking cow's milk diluted one-half. It was the custom of the mother to Pasteurize a fresh supply in the evening for the baby's use during the night. The baby did not nurse more than twice. The milk was heated in separate bottles, submerged in hot water and then cooled, and the bottles were wrapped in a light woollen blanket and kept at the foot of the bed—a most convenient, if not entirely scientific, method of preserving milk. This did very well during the cold months, but as the weather became warmer the practice had to be discontinued and the milk kept on ice and heated as required. Almost the first warm night, the baby, after drinking his milk as usual, was taken sick and vomited thick, hard masses of sour curd. Exactly the same milk was used, and on investigation I could find no reason, either in the cow or its food, and so was satisfied to ascribe the trouble to a fermentation which had occurred on account of the heat in the room. The dilution of milk with lime water or attenuants, which has for years been generally practised with good results, undoubtedly acts by neutralizing the acid of fermentation, so that an excess of acids is prevented.

I have alluded to the contamination of the milk in the barn, and have demonstrated that milk may be made practically sterile. There yet remains the trans-

porting of the milk to the consumer and, a phase of the subject not often alluded to, the preservation of the milk in its purity in the home where it is to be used. Many dairymen now employ glass bottles, with a metallic or ligneous cap, and if the bottles are properly washed before the milk is put into them the plan is an excellent one and should be made compulsory. Milk properly strained, cooled, and bottled, kept at a low temperature in the house, and exposed no more than absolutely necessary, will keep sweet twenty-four hours.

Instead of this, consider for a moment our present methods. The milk is put into large cans, carted about the city here, there, and everywhere, in the dust and dirt of the business quarters, and the hot, close, unhealthy atmosphere of the tenement districts, uncovered and exposed at each stopping-place. The milk is poured into a can or pitcher, possibly not over clean, and then perhaps left on the doorstep until the cook has time to get it, or kept in the pantry or on the windowsill in the sun.

Given a milk declared by competent authority to be germ free as it leaves the barn, how long think you will it remain so? If we could have at hand a pure milk, cooled, bottled, and kept cool, I believe our results in infant feeding would be better than they now are. The fact that there is a chemical and physical difference between human and cow's milk is not the only difficulty. A child may to a certain extent adapt itself to a slight chemical difference, and we have repeatedly seen a child do well on its mother's milk when that milk analyzed would fall far below the average of human milk. Adriance[1] gives analyses of several specimens of milk which, compared with the normal standard, would be considered abnormal, and yet babies fed with it were gaining in weight and appeared healthy.

The personal idiosyncrasy of the child is an important factor, and when a child thrives on a milk of unusual percentages of fats and proteids it does so because the milk is good for that particular infant. I would not discourage the chemical examination of milk in arranging a diet for a child, but I would emphasize the importance of having a good milk. Of what use is the fact that we have the proper percentage of the several constituents of breast milk, if that milk is also loaded with germs of fermentation? We cannot always be sure of our exact chemical relations; we can be and should be absolutely certain that the milk is good and pure.

The particular aerated milk employed in the experiment was delivered in bottles early in the morning, and its production was a matter of thought and care in every detail. Even with milk produced and preserved under the most favorable conditions, dilution could not be entirely avoided; the natural size of the particles would prevent that; but the milk could be given stronger, and so much of the trouble from too little fat would be overcome. Budin, by means of sterilization with Soxhlet's apparatus, is enabled to give whole milk to even very young children, by giving only such quantity as the stomach will easily tolerate. This, although sterilized milk is now no longer used as a continued diet, emphasizes the fact that many of the difficulties in infant feeding are due to conditions favoring an acid fermentation of the milk employed.

That milk should ferment on exposure is entirely consistent with our present knowledge of the germ theory of suppuration and fermentation in wounds. Exactly the same principles apply to milk as to any tissue of the body. To-day a surgeon who should undertake an operation of almost any grade and neglects the principles of asepsis or antisepsis, would be considered behind the age, if not criminally liable. The influence of bacteria on healthy tissue is now understood and appreciated, and it is only necessary to witness the technique of a modern scientific operation to realize that no detail is too trivial which will the more effectually prevent infection of the wound. Surely we cannot plead ignorance, in neglecting this important question, of the proper care and management of milk, especially that intended for infants and invalids.

As one carefully considers this subject of cow's milk in infant feeding, and realizes the close intimacy of the mortuary statistics with the milk question, the desire for good milk becomes intensified, particularly when we contemplate the misery and sickness directly traceable to poisoned milk and are confronted with the fact that artificial feeding is on the increase. That a large part of the mortality in cities is traceable to cow's milk is proven by statistics. Dr. Coit, in a paper on the "Causation of Disease by Milk," says:

"It is claimed that twenty per cent. of all who are born to man in large centres of population die during the so-called nursing period; that nearly thirty per cent. of all deaths in many large cities from all causes and in all periods of life are infants of the first year, due to a lack of physical resistance in city children, resulting from a want of suitable food; that it has been claimed that sixty per cent. of children, hand fed during infancy, perish before they are five years of age; that the mortality from nutritional disorders, directly or indirectly, during the first year, comprises nearly ninety per cent. of the whole; that so-called cholera infantum and the summer diarrhœas among children are now regarded by authorities to be largely due to milk infection."

It is an encouraging sign of progress, however, that the efforts of such men as Coit, Rotch, Snow, Vaughan, Leeds, and others are bearing fruit, as evidenced by the number of certified milk farms now in active and successful operation in various cities of this country, under the direct supervision of a commission of physicians, chemist, bacteriologist, and veterinary surgeon. And that their efforts are entirely successful is proven by a case reported in a recent article received from Dr. Coit in answer to a question asked by the writer:

"A Newark physician desired to have a baby supplied with fresh milk during an ocean voyage. Accordingly, on May 11th, he ordered twelve bottles delivered on board a steamer. With these he sent twelve other bottles, asking the steward to keep them on ice till the steamer should return to New York. This was done, and on May 31st they were handed over to a member of the commission. One bottle was opened and the milk found to be sweet. Other bottles were sent to the chemist and bacteriologist, and found to be in a remarkable state of preservation. Three days later, when the milk was twenty-four days old, it was tasted by a number of physicians and found to be perfectly sweet."

Such results cannot be passed over lightly. They emphasize the importance of the cleanliness in detail, exercised at a certified milk farm, in the production of milk for infant feeding. I would that such farms were more general.

Epsom Salts.—The stomach will not reject it if prepared in this way: Put a tablespoonful in a teacup and add two or three tablespoonfuls of boiling water, stir well, decant, and reject the residuum. Add a little lemon juice, let the mixture cool, and give to the patient. If in the country, beyond the reach of lemons, vinegar will make a fourth-rate substitute. Repeat the dose every four hours until the bowels respond. The quantity of water may be varied to suit the caprice of the patient.—PARCELLS.

Clinical Department.

TRIPLETS.

By ABRAHAM GOLTMAN, M.D., C.M., L.R.C.P.S. Ed.,

NEW YORK.

Mrs. Mary M——, aged twenty-two, pregnant for the third time, came to me on March 1st, stating that she was in her last month and "carrying the child high." Her history showed that her previous labors were precipitate.

On examination the abdomen was a great deal larger than could be accounted for at the ninth month, reaching up to near the xiphoid cartilage. There was a considerable amount of suprapubic œdema. The abdomen was very prominent and more developed in its transverse diameter. There was present slight œdema of the lower limbs. Fœtal movements could be made out at different parts of the abdomen.

On palpation the abdomen was hard and resisting, and I could make out the breech of one fœtus at the fundus on the right side, and the head of another on the left side. On further palpation I made out on the lower and right portion of the uterus the head corresponding to the breech.

On auscultation fœtal heart sounds could be made out on the right side of the uterus on a line with the navel, synchronous with the mother's pulse. After some difficulty I made out fœtal heart sounds on the left side on a line running from the middle of Poupart's ligament to the navel. The heart sounds, at these two places, were not synchronous with each other, but were so with the mother's pulse.

From the above results I suspected twins. On March 15th I was hurriedly called to see her, at 10:30 A.M. She stated that her bag of waters had come away that morning at 4:30, and that she was now in pain. I made a vaginal examination and found the os fully dilated and diagnosed a first position. Pains were irregular and weak. After stimulating the uterus to contract with hot-water douches, the head was delivered in the first position, and very rapidly the whole child was expelled at one or two sharp pains. The child was very cyanotic and phlethoric, and the pulsations of the cord were feeble. After trying artificial respiration, with the aid of cold and hot water douches, I succeeded in resuscitating the child. On returning to deliver the placenta, I found the uterus as large as before labor set in. I examined per vaginam and felt a foot presenting at the os through the membranes. The patient was now exhausted; pains had entirely ceased. I gave her a drachm dose of fluid extract of ergot with hot vaginal douches and waited half an hour; pains did not set in. I repeated the dose and she then had a return of pains. The membranes were ruptured, and with the flow the breech of a second infant was delivered rapidly, the head remaining grasped by the vaginal opening. After strong flexion of the head was practised, it was delivered without any difficulty. After the cord was tied the woman complained of severe pains and something "between her legs," which I found was a bag of membranes protruding at the vulva and containing a fœtus head first, which also was delivered rapidly, the placenta following at the same time. Injections of strychnine were now given, the uterus became well contracted, and a drachm of ergot was repeated.

The last fœtus was a male, and appeared to be prematurely born. The first cried but little and was very cyanotic. The other two were of natural color. Each fœtus had hardly any caput succedaneum, and none was fully matured. The placenta weighed twenty-five ounces and contained three amniotic sacks, each having separate cords. The cord corresponding to the first fœtus was shorter than the other cords, more congested, tortuous and thicker. Where it entered the placental tissue, that portion was congested, dripped blood, and tore easily, and could be readily distinguished from the remaining placental tissue.

The following day the first child had several hemorrhages (epistaxis), and died twenty-four hours after. So far the two others are doing well and nursing. The mother is progressing favorably. The children were all males.

1612 Lexington Avenue.

HICCOUGHS AND THEIR TREATMENT.

By LUKE FLEMING, M.D.,

TARRYTOWN, N. Y.

In view of the serious cases of hiccoughs reported from time to time, I am led to give the history of the following case and also the treatment employed, in the hope that it may be of benefit to others.

A. M——, female, fourteen years of age, fairly healthy and of good family history, was attacked on the night of May 3d with hiccoughs, the attack consisting of three or four paroxysms of half an hour's duration each, which ceased on the following morning. Toward the afternoon of the same day the paroxysms reappeared, increasing in severity until in the evening the exhaustion of the patient frightened the parents and I was called. At this time she had been hiccoughing continuously for two hours and had just recovered from an attack of syncope. During the faint the hiccoughs ceased, but returned upon her regaining consciousness. Her temperature was normal; pulse rapid, feeble, and irregular; and her general appearance that of extreme prostration.

While watching her I remembered her as a patient whom at one time I had treated for malaria, and in whom quinine had caused a most unbearable urticaria. It occurred to me now that if I should again prescribe quinine and induce this urticaria I might so disturb her nervous system as to cure the hiccoughs. Acting upon this thought, I gave ten grains of the drug. During the ensuing two hours her hiccoughs grew worse and her condition became so alarming that the parents feared death. At the end of that time, however, a scarlet rash spread over her body, her fingers and face puffed, and an intense itching came on. At the onset of this rash the hiccoughs promptly ceased, and although but one dose of quinine had been given and the rash lasted only three hours, the hiccoughs did not return.

In thinking of this case it strikes me that the treatment of hiccoughs by nerve sedatives is unwise, and that a more rational treatment would be by nerve irritants. If I may use a figure of speech, we might compare the nervous system of a patient suffering from hiccoughs to an indolent garrison in an enemy's country allowing a crazy gunner to exhaust all its ammunition by firing salutes to the sun. By throwing a shell into its midst we awaken it from its lethargy and stop this foolish pastime. So, in a case of hiccoughs, the nervous system is not attending properly to its duties and is exhausting its vitality in a harmful direction. By employing some means that will give it a thorough shaking up, we awaken it to its danger and restore its normal action.

In the above case this result was obtained by the idiosyncrasy of the patient to quinine. In other cases we might seek some like condition and utilize it.

Hospitals for Hagerstown. — The authorities of Salisbury and Hagerstown, Md., contemplate the building of hospitals in these towns.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, July 3, 1897.

DISINTERESTED TESTIMONY ON THE DISPENSARY QUESTION.

THE *Evening Post* of June 19th contained an interesting account of a visit to the Vanderbilt Clinic. The reporter seems to have been a fair-minded person, with no particular theory to prove but with only a desire for facts. He introduced himself to the superintendent of the dispensary, told him that he "simply desired to observe the patients as they entered and left, and that this was to be for the purpose of a description which might form the basis of some judgment as to whether the assertion concerning the character of many persons treated at the clinic were true." The superintendent gave him a note to the clerk of the clinic allowing him to look on, but restricting him to simple observation and not allowing him to be "obtrusive," which, however, he did not think the reporter desired to be. The latter spent two hours in the clinic, and his observations may be presumed to be a fair statement of what happens in this particular institution from day to day.

He estimates the number of applicants during his visit to have been about four hundred.

"Nobody was seen to arrive in a carriage, nor was any finely dressed man or sumptuously attired and adorned woman discerned in the crowd. But, on the other hand, those whose dress and appearance denoted an extreme degree of poverty were certainly in a very large minority. It is difficult to resist the conclusion that not more than one in twenty-five—the pen is tempted to write one in fifty—of the applicants treated at the Vanderbilt Clinicon the afterno on of observation was a legitimate patient. Not more than one in fifty was at all shabbily dressed. A large majority were fairly well dressed. A third of them, it will be safe to say, were quite presentably dressed. A few—perhaps as many as a fifth—were dressed positively well. Much the greater number of the patients were women. Brightly flowered and feathered hats abounded. A silk waist or a silk skirt was no uncommon sight. Many of the women carried pocketbooks in their hands, quite as women do when they go shopping. A good many of them also carried satchels, not a few of which were decent enough looking. Umbrellas—most of them apparently good, sound specimens, and some of them of silk—were seen repeatedly. Jewelry was by no means absent. Breastpins, earrings, chains, bracelets—seemingly of gold—were easily to be seen. One woman, particularly observed, was handsomely and stylishly dressed in black. At her throat was a breastpin that looked like a gold one; around her neck was a black chain ornamented with gold or the semblance of it; about her wrist was a heavy coiled bracelet, apparently of the same precious metal. Her hands were encased in black kid gloves, her hair was carefully and modishly arranged, her bonnet harmonized with her dress, and her whole appearance was that of a person in thoroughly comfortable circumstances. She was not rejected. She received advice and a prescription, and waited patiently until her turn came to have the latter filled, when, like the rest, she laid down her ten cents and received her medicine.

"A considerable number of children was present, either as patients or merely accompanying parents. The most of these—or, to be conservative, at least half of them—were, to all appearance, well and tastefully dressed. At any rate, lace and ribbons were frequent adornments of their caps and dresses, and there was not the slightest hint about them of dire poverty. The men, on the whole, seemed less well off than the women, yet some of them were presentably clothed. One very decently attired man asked the superintendent of the building to expedite his turn at the pharmacy, as he was compelled to get back to his work on a street car. The superintendent obliged him. A colored man wearing a neat bicycle suit with golf stockings, and riding an almost new-looking 1896 bicycle ($100 make) (which, at the suggestion of the superintendent, he brought in with him, and put in a room reserved for bicycles), was one of the patients treated. He hung around for a long time after getting his medicine, and, when questioned by the superintendent as to why he lingered, replied that he was 'waiting for a lady who had accompanied him.' Another thing noticed was that the change returned at the window of the pharmacy not seldom included bills as well as coin. In short, it is believed that few impartial spectators could have resisted a feeling of scepticism concerning the absolute inability of most of these people to employ physicians privately, especially as it is the almost invariable rule of practitioners to take into consideration the circumstances of their patients (as the rich ones know)."

The writer of this article, being of a temperate mind, does not claim to have solved the problem of dispensary abuse, and shows his fairness by giving the views of those in charge of two of the dispensary services of the city, the clinic above alluded to and the Demilt Dispensary. The great inquiry which always comes up in discussions on this subject is, why not employ the resources of the Charity Organization Society in an effort to separate the worthy from the unworthy? To this question, in the present case, no conclusive answer was given. It is said that it is "more feasible to get along without the society's aid than with it." Under the word "feasible" come up the questions of delay in reporting upon a given case and the expense to the medical institutions of carrying on such inquiries. In reply to this it may be said

that no advocate of reform in this matter has ever advised waiting for inquiry to be made in cases manifestly needing immediate attention. Such attention should be given at once. The case could be investigated later. In regard to expense, of course it would cost something, but such a sifting process would greatly lessen the number of cases requiring charitable aid. The managers of dispensaries need to be constantly reminded that the true object of dispensaries is to treat those who are sick and unable otherwise to obtain proper care, not to see how many cases can possibly be gathered in.

The most discouraging thing of all is the absolute indifference of managerial boards to this burning question of the hour. They do not seem to think that it is of sufficient importance to call for consideration. They do not care about it. If they did, they would do something. In these days when social questions are receiving such careful consideration at the hands of our best thinkers, the institution manager, with power to do so much in the right direction, does absolutely nothing and seems unwilling that any one else should further the progress of reform along this line.

SUSCEPTIBILITY OF INFANTS TO HOSPITALISM.

In a pamphlet on "The Babies' Ward, New York Post-Graduate Hospital," Dr. H. D. Chapin points out the dangers to which infants are subjected by a lengthened stay in a hospital. In reference to admitting babies to these institutions under any circumstances, he says: "Entrance to a hospital should be limited to acute cases of illness, and discharge should take place immediately upon recovery, even if the latter is only partial. A speedy or satisfactory convalescence is impossible for an infant in a hospital. The earlier the age, the greater is the susceptibility to hospitalism and the quicker it ensues." This warning is well timed and one to be seriously regarded. There is a too great tendency on the part of parents and relatives to place infants when unwell in hospitals. This is often done to evade responsibility and trouble, although of course in many instances the only motive is the good of the child. On account of the great sensitiveness of a child's organism, it is absolutely essential that the young should live in the most healthful conditions. Pure air is of more importance for the maintenance of health in children than in grown-up persons. To quote again from Dr. Chapin: "Outbreaks of contagious diseases are constant dangers in hospitals for infants and children, and can be guarded against only by the greatest care. Diphtheria, measles, and pertussis are, from the nature of these diseases, most liable to creep in. Visitors, however, are often responsible for the bringing of contagion, and all possible safeguards should be thrown around this source of danger, and children should be refused admittance absolutely. The hygienic surroundings must be of the best, the nursing of a very high grade, and a most scrupulous and painstaking oversight exercised. One good nurse should be supplied to not more than four or five sick infants, and in some cases one nurse may be required for only two patients. Finally the infants should be particularly watched for the first sign of hospitalism and promptly discharged before the malady has time to gain any hold on them." The extreme susceptibility of children to contagion when congregated in large numbers has been conclusively proved time after time. An example in point is that of l'Hôpital Trousseau in Paris. This hospital for children contains upward of five hundred beds, and is located in the heart of a dense working-class population, so that its wards are constantly filled. A high municipal official some time ago, referring to the conditions prevailing in l'Hôpital Trousseau, said: "As to the hospital Trousseau, I shall use my strongest endeavors to have it abolished. I see continually how badly the system works. It is a veritable hotbed of infection, and children are there hospitalized in the most, it might almost be said, homicidal manner." These words might be applied with equal truth to many institutions for children much smaller than the hospital Trousseau. For many reasons into which there is no space to enter here, it is always undesirable to have young children living together in large numbers. To keep the rooms which they inhabit in a sanitary state is almost an impossibility. Hospitals for children on a large scale are a great mistake. The larger the hospital the greater the mistake.

MEDICAL EDUCATION IN AMERICA AND GREAT BRITAIN.

But a few years ago, and it would have been absurd to attempt to compare medical education in any part of America with that in England. There were then no points of comparison; the English standard was far higher; in fact, with very few exceptions, the standard of medical education here was so low as to be scarcely worth speaking about. The strides made in late years in many of the States have been phenomenal. So much so has this been the case that it may be said without exaggeration that a revolution in the training of medical men has taken place in these States. New York is well to the front in this matter, and a comparison instituted now between some of the British schools and those of New York would not result altogether in favor of the former. In Great Britain the course of medical education is controlled by an act of Parliament, which is strictly applied to the whole country. In America there is no central law governing the practice of medicine. Each State does what it pleases. Medical schools have been multiplied without reason, the profession is overcrowded, and as a natural result many of those with licenses to practise are incompetent. In Great Britain there is a medical school to about 2,300,000 of the population, while in this country there is one to 440,000. The medical course in the United Kingdom has been lengthened to five years—four years' attendance at a recognized medical school, and attendance at the clinics of a hospital or private practice for the fifth year, so that the English medical training is longer by a

year than that required in New York State, although the custom of serving as interne in some hospital for a year or eighteen months after graduation makes the course here practically longer than in Great Britain. There are eleven universities in Great Britain which have the privilege to grant degrees in medicine, and, in addition to the universities, licenses to practise are granted by the Royal Colleges of Surgeons and Physicians in each county, and by the Society of Apothecaries of London; all these must conform to the Medical Council's standard, which is now a high one. Each degree, however, carries with it a value of its own; this fact, although not appreciated by the general public, is recognized by the profession itself. The degree of doctor of medicine of London University takes the highest rank. Of the qualifications, the fellowship of the Royal College of Surgeons, England, and the membership of the Royal College of Physicians, London, stand first. The joint qualifications of the membership of the Royal College of Surgeons and the licentiate of the Royal College of Physicians take about the same rank as an ordinary university medical degree, that of the University of London excepted. Of the various schools London is the best for practical work, and Edinburgh for theoretical. It has been suggested that the plan pursued in most of the States of the Union, of compelling a man before he is allowed to practise to pass a State examination, should be adopted in England; but for many reasons the project has fallen through. In America more attention is paid to a thorough study of bacteriology than in England. That subject has been greatly neglected there, although now the great practical use of a knowledge of it is recognized by the medical schools throughout the country, and in London there are several well-equipped bacteriological laboratories where it is possible for a student to undergo a regular course of instruction. Post-graduate courses have also been instituted.

To compare the teaching in the medical schools of the United States and the value of the State license with those of Great Britain would be a very difficult task. In the United Kingdom, although a certain standard fixed by the Medical Council has to be reached, there is not the uniformity guaranteed by the State examination, and much diversity of opinion exists as to which degree after that of London University is the best. The course here, only that it is a year shorter, is much the same as in England; the other difference is that in most of the United States the final examination is conducted under the auspices of the State itself, whereas in Great Britain it is in the hands of private corporations. There cannot be much room for doubt as to which is the better plan.

The German Gynæcological Society.—The seventh congress of the German Gynæcological Society was held this year at Leipzig, on June 9th and two following days, under the presidency of Professor Zweifel. Among the subjects discussed were retroflexion of the uterus and placenta prævia.

News of the Week.

The International Medical Congress.—Dr. A. Jacobi writes: "A letter received from the secretary-general of the Twelfth International Medical Congress conveys the following information, which is additional to that which has been published in the medical journals. As it is too late to send tickets to the American congressists, they are requested to send to the secretary-general at Moscow their addresses in London, or Berlin, or Vienna, or Paris, or to avail themselves of the national committees in those cities in order to receive their tickets and free passes over Russian railroads. The free passes are valid from July 13th to September 13th, over the following routes: Eydtkunen to Moscow and back; Moscow to St. Petersburgh, or Moscow to Graviza, or Moscow to Odessa, or *vice versa;* Graviza to Warsaw to Moscow and return by Moscow to St. Petersburgh (or Odessa, or Eydtkunen, or Ungheri, or Alexandrowo), or *vice versa.* Different lines, going and returning, may be chosen, and stop over is permitted. The trip from Eydtkunen to St. Petersburgh is excluded from the free list.

A New Annex to St. Vincent's Hospital.—The sisters of charity have opened at Jarvis Lane, Far Rockaway, their new annex to St. Vincent's Hospital, New York. The old Jarvis Homestead has been transformed into a convenient retreat, more particularly for convalescents. The sanitary arrangements of this country branch are perfect. The rooms are large and cool, and afford a fine view of the ocean. The grounds are spacious and well shaded. Although only three minutes' walk from the railroad station, this new home is situated in a secluded spot. The sisters are aided by a staff of trained nurses in the care of those placed under their charge.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C. Changes in the medical corps of the United States navy for the week ending June 26, 1897. June 24th.—Passed Assistant Surgeon G. B. Wilson detached from the *Yantic*, ordered home, and granted two months' leave.

Medical Society of New Jersey.—At the one hundred and thirty-first annual meeting of the Medical Society of New Jersey, held at Atlantic City, on June 22d and 23d, the following officers were elected for the ensuing year: *President*, D. C. English, of New Brunswick; *First Vice-President*, C. R. P. Fisher, of Bound Brook; *Second Vice-President*, Luther M. Halsey, of Williamstown; *Third Vice-President*, J. H. H. Love, of Montclair; *Corresponding Secretary*, E. L. B. Godfrey, of Camden; *Recording Secretary*, William Pierson, of Orange; *Treasurer*, Archibald Mercer, of Newark.

Colorado's Contribution to the Rush Monument Fund.—Colorado has already fulfilled the pledge for a $2,000 contribution to the Rush monument fund, made by Dr. Graham, at the meeting of the American Medical Association at Philadelphia. At the meeting of the State Medical Society, June 15th, the full sum

pledged by Dr. Graham was immediately raised by individual subscriptions offered most generously and with great enthusiasm.

The American Institute of Homœopathy met in annual convention in Buffalo, on June 24th and following days.

Dr. Charteris, professor of materia medica in Glasgow University, died on June 7th, at Comrie, in Perthshire, where he had gone to recuperate after an attack of influenza.

Dr. Chancellor, of Baltimore, lately United States consul at Havre, has returned to this country.

Dr. T. Mitchell Prudden, of this city, received the degree of LL.D. from Yale University on June 30th.

Hospitals for Contagious Diseases in London.—The hospitals of the metropolitan asylums board, in London, have 3,800 beds set apart for scarlet fever, and only 700 for diphtheria.

Dr. Paul L. Post has been appointed fourth assistant physician to the New Jersey State Hospital.

The Connecticut State Medical Law, which went into effect on the first of this month, provides that no person shall receive a certificate of registration until he has passed a satisfactory examination before one of the three examining committees appointed for that purpose. These committees consist of five members each. The examinations, which must be in writing, will be required in anatomy, physiology, chemistry, materia medica, hygiene, obstetrics, and medical and surgical pathology, diagnosis, and treatment. The penalty for violation of this law is a fine of not less than $100 nor more than $300 for the first offence, and for each subsequent offence not less than $200 nor more than $500, or from thirty to ninety days in the county jail. One-half of the fine collected goes to the person or persons making the complaint and the other half to the State board of health. New York doctors have been diligent in securing the right to practise in Connecticut under the registration law of 1893, according to which no examination was necessary. This explains the enormous increase in medical practitioners with which Greenwich, the nearest town to New York City, would appear to have been afflicted. There were thirty-one registrations in the entire State in April, of which twenty were in Greenwich.

A Humane Execution.—An Italian was put to death at Auburn on June 22d, for the murder of a fellow-countryman eighteen months ago. He was placed in the chair, and five shocks with a current of eighteen hundred and forty volts, each of about one minute duration, were made at intervals. The poor creature was not pronounced dead until eight minutes had elapsed after the first contact was made. The five shocks were necessary because of the imperfect contact of the electrode on the man's leg. The smell of burning flesh was quite distinct in the chamber after the first shock had been given.

The Philadelphia County Medical Society.—At the final stated meeting for the season of the Philadelphia County Medical Society, Dr. A. G. Thomson presented the report of a case of complete blindness due to acute poisoning from overuse of Jamaica ginger, followed by toxic amblyopia of the ordinary chronic form. Dr. A. A. Eshner read a paper on "Hysteria in Early Life," in which he detailed the histories of a small group of cases occurring in girls at and before the age of puberty, and displaying more or less characteristic features of the grand neurosis. Dr. Henry Beates, Jr., made remarks on some of the common causes defeating the proper progress of therapeutics.

The Health Board at Dead Man's Curve. — The grand jury and the district attorney having been unable to stop the needless sacrifice of life at the various curves of the cable roads in this city, the health board has taken the matter in hand. At a meeting held June 29th, the following amendment to the sanitary code was proposed for adoption: "No conductor, driver, or gripman of any railroad car or other vehicles running on tracks in the city of New York shall allow or cause the same to be pulled, drawn, or propelled on or around any curves on any public street or avenue at a greater rate of speed than two miles an hour. And no director, president, superintendent, or other person who is interested in or who owns or controls any such car or vehicle shall permit it to be pulled, drawn, or propelled. This section of the sanitary code is adopted for the purpose of preventing accidents by which life or health may be endangered." According to the rules, this resolution must lie over a week before it can be acted upon.

The Late Dr. William T. Lusk.—The faculty of the Bellevue Hospital Medical College have the painful duty of directing a formal record in their minutes of the untimely and sudden death of their beloved colleague and president, the late Prof. William Thomson Lusk, on June 12, 1897. Dr. Lusk was an alumnus of the college, class of 1864, and class valedictorian. He became one of the instructors in the summer session in 1870. He was appointed professor of obstetrics in 1871, and president of the faculty in 1889. His great ability as a teacher and voluminous writer commanded the respect and admiration of the profession at home and abroad. His public services in the institutions under the charge of the commissioners of public charities were rewarded by the appreciation and gratitude of all interested in medical charities. His devoted work in behalf of medical education connected his name most prominently with the teaching of medicine, and especially with the Bellevue Hospital Medical College. But, above all, his fearless honesty of purpose and his exquisite gentleness of character and manner so endeared him to his associates in the college that we, his loving colleagues and friends, feel in his death a personal bereavement which words fail adequately to express. In common with his family, the profession, and his many devoted friends, we mourn his loss and deplore the premature end of a most useful and valuable life.

AUSTIN FLINT, *Secretary.*

Society Reports.

CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

FOURTH TRIENNIAL SESSION.

Held in Washington, D. C., May 4, 5, and 6, 1897.

WILLIAM H. WELCH, M.D., OF BALTIMORE, PRESIDENT.

(Concluded from Vol. LI., page 916.)

AMERICAN ASSOCIATION OF GENITO-URINARY SURGEONS.

Second Day—Wednesday, May 5th.

Priapism.—DR. R. W. TAYLOR, of New York, read a paper with this title. In normal conditions erections last a short time only; in certain morbid conditions this erection is much prolonged and to this prolonged erection the term priapism is applied. It may be divided into: 1. Priapism in infants and children from reflex causes. 2. In adults symptomatic of stone in the bladder or urethra, of stricture of the urethra, or retention. 3. Symptomatic of gonorrhœa. 4. Due to cantharides. 5. Essential priapism.

The first four are not the subject of the present paper, but the fifth form, essential priapism, may be divided into four varieties as follows:

1. From injury to spinal cord or to perineum.
2. Symptomatic of cerebral or descending cord disease.
3. Occurring after alcoholic and sexual excesses.
4. Cases occurring in persons of general good health, with no apparent adequate cause, but now by some attributed to leukæmia.

In the cases resulting from spinal injury the course depends upon the extent and severity of the injury. In some cases recovery occurs and the priapism ceases; in others death occurs without relief from the priapism. The cases of priapism from cerebral and descending spinal disease are rare and few in number, and in most of the cases reported the priapism was of very long duration. In the cases from alcoholic and sexual excess the mode of onset is variable, in some cases sudden, in others more gradual; but in all the condition is persistent and temporarily obstinate, and in many of them very painful, with swelling and often a nodular condition of the penis. Often there are marked tenderness over the perineum and at the bulb, and spasm of the cremaster muscle. The pain also, as distinct from the tenderness, is often very severe, and there will be difficulty in passing the urine, and more or less general systemic depression and prostration. Generally not the whole organ is involved. The invasion is usually sudden and the involution usually slow and gradual, with many relapses. While the etiology is not yet clearly established, it would seem that in most if not in all cases there has been some injury to some part of the penis itself, or marked irritation of the sexual centre, or of the nervi erigentes, or of the sympathetic.

In regard to the class of cases stated as possibly due to leukæmia, Dr. Taylor was not yet fully convinced of the certainty of the relation between the two conditions, and thought that possibly they might be merely coincident, the priapism being due to some other cause or causes, and urged more careful investigation of the previous history of these cases.

The prognosis was always somewhat uncertain and depended upon the cause. In cases due to injury the treatment by incisions would usually greatly hasten recovery. In the spinal cases the prognosis must be very guarded. In the neurasthenic and so-called leukæmic cases the priapism was likely to be very persistent, and liable to relapse.

Treatment: There could be no regular routine treatment. Chloroform, ice, electricity, and leeches, as a rule, were unsuccessful. Dr. Taylor's preference was for early moderate incisions into the most turgid part, or parts of continuous pain, or into nodular masses that might be present probably as a result of traumatism. Bromides and other sedatives during the paroxysms were of advantage. Locally hot baths, hot and cold spinal douches, sponging with hot water or anodyne poultices might be of service.

DR. LEWIS, of St. Louis, reported a case of priapism cured by ligation of the dorsal arteries of the penis, and Dr. White, of Philadelphia, suggested the use of thyroid extract, disclaiming, however, any experience with it in this condition.

Chronic Contraction of the Prostatic Fibres Encircling the Vesical Neck.—DR. EUGENE FULLER, of New York, read the paper. In defining the condition, Dr. Fuller noted the distinction between spasm of the vesical neck and the true contraction (from the standpoint of his paper), viz., that spasm is but a momentary condition, while contraction indicates a somewhat more lasting (sometimes continuous) tonicity, and both are distinct from the "pain" in the neck of the bladder, which is known as neuralgia of the vesical neck. Spasm is purely functional and is not permanent, and is associated with no pathological change. The contraction mentioned in the title of the paper represents a definite pathological condition, but bears a relation to the spasm, in that long-continued or very frequently repeated spasm may be a causative factor in the production of the contraction. The lesion is comparable to that in the sterno-cleido-mastoid muscle in chronic torticollis. If perineal section is made under full anæsthesia, a hard inelastic ring-like contraction is felt by the finger, very different from the feel of the normal vesical neck. The calibre is large enough readily to admit a good-sized sound, and therefore cannot be determined by examination with that instrument. One cannot force the finger into the bladder without tearing the ring, or first cutting it, preferably through the floor. There is no evidence of prostatic enlargement, either in examination by rectum or through such a perineal wound.

Dr. Fuller has had no opportunity to make a histological examination of the lesion, as there have been no deaths among the observed cases this far. The principal clinical symptom is the partial or complete inability to pass urine, which inability is of gradual and intermittent development, beginning with hesitancy and dribbling and finally resulting in attacks of complete retention, requiring the catheter to empty the bladder; and later the constant use of the catheter becomes necessary. This development may take three or four years. Diagnosis must be made from the clinical history and by exclusion of other (usually acute inflammatory) causes of obstruction to urination. The only positive evidence, however, is the digital examination of the neck of the bladder through a perineal section, at which time also the disease may be corrected by thorough incision of the contracted ring of fibres. In many cases there are also a clinical history and evidence of trouble with the seminal vesicles, or with the ureter or the kidney (*e.g.*, chronic pyelitis), or possibly of the rectum. Most cases occur in patients between twenty-five and fifty years of age. The only treatment found available by Dr. Fuller is thorough divulsion or cutting of the fibrous ring at the neck of the bladder, putting in a perineal tube for drainage of the bladder and to give it complete rest for a period varying according to the case.

Dr. Fuller said he had found no literature on ex-

actly this subject, and, comparing his cases with those reported by Belfield and Post, pointed out the differences between them and his cases as reported.

Dr. Chismore detailed one or two cases of similar character, in which operation had not effected a cure, and felt that the condition was to a large extent a neurotic one.

Dr. Alexander gave it as his judgment that the condition was due not to contraction of the fibres about the neck alone, but to a hardening or contraction or fibrous condition of the whole substance of the prostate; that the sudden attacks of retention were the result of congestion, and that the operation relieved the condition by reducing the congestion. He had noticed clinically three forms or conditions of the ring: 1st. When it was still soft and elastic, but slightly harder than normal. 2d. When it presented some resistance at first to the entrance of the finger, and then suddenly gave way, splitting in a stellate manner. 3d. When it was very dense and hard, and would not admit the finger at all. In the first and second conditions relief was obtained by dilatation; in the third only by incision. But he felt that the complete division of the ring was not entirely harmless, as he had seen a condition of incontinence following it, although in these latter cases the patients were in a poor and low condition of general health.

Dr. Bryson spoke of the unfortunate lack of opportunity to get at the exact pathology by post-mortem examination. He reported several cases similar to those of Dr. Fuller, and spoke of one of them particularly, in which with almost the same train of symptoms he had found a very much hypertrophied veru montanum. He suspected tuberculosis in this case and later found a descending tuberculous ureteritis. In connection with this case Dr. Bryson spoke of the relation between diseased conditions of the kidney and ureters, and bladder manifestations resulting from them, and gave it as his experience and opinion that there occurred no pain, frequency, or tenesmus (as a result of disease in kidney or ureter) unless the lower third of the ureter was involved.

Dr. Bangs said that he found cases, such as Dr. Fuller had described, not at all uncommon. He thought that the etiology was traceable to some antecedent trouble of an inflammatory character in the prostatic urethra, or to some sexual disturbance. In the case of retention and residual urine, the bladder must have drainage and rest for a sufficient time to restore the harmony of action between the detrusor and the sphincter.

Tuberculous Necrosis of the Prostate.—Dr. Fuller read a second paper on this condition, which he said was not common, most of the cases usually classed as such being a tuberculous condition of the adjacent structures, the prostate itself not being involved. The prostate is very rarely primarily tuberculous. Dr. Fuller had seen two cases recently, in one of which there was a small focus of necrosis in the body of the prostate, and in the other the entire prostate was in a condition of necrosis. Resolution of tuberculous necrosis is not improbable, either by the area affected becoming encysted, or by its breaking down and discharging freely into the urethra or rectum.

A New Method of Removing Vesical Polypi.—Dr. George Chismore, of San Francisco, read a paper with this title. The principle involved is suction, by means of an aspirator attached to an ordinary litholapaxy catheter, the aspirator being a strong, thick, rubber hand bulb. The bladder is injected with three or four ounces of boric-acid solution, with cocaine, four per cent.; and then the catheter is passed, and the polyp is caught by suction in the eye of the catheter; when it is caught, the catheter is held quiet for a moment to get a firm hold, and then by a slight swaying or sawing movement, combined with slight traction, the growth is loosened from its attachment to the bladder wall and passes through the catheter into the receptacle attached to it between the hand bulb and the proximal end of the catheter. When a polyp is caught, the "feel" is different from that noted when the eye of the catheter is in contact with the bladder wall; in the latter case one can feel the slight thud and then the catheter seems firmly fixed, and at the same time there is a cry of pain from the patient; when a polyp is caught there is no pain, the "thud" is absent, and the catheter is not firmly fixed, but usually freely movable, especially if the growth is pedunculated. The polypus usually is detached from the bladder wall very easily, with very little traction force. After the removal of the growths by this method, the hemorrhage ceased at once in the two cases reported, and up to date (three years after operation) there has been no recurrence of symptoms indicating the presence of any subsequent development of the polypi.

Dr. Bryson remarked that he had never yet seen a papilloma of the bladder that did not sooner or later degenerate into a malignant condition.

Rapid Formation of a Vesical Calculus. — Dr. William Judkins, of Cincinnati, Ohio, reported a case of vesical calculus in a child about five years old. A stone was found with a searcher and removed by suprapubic cystotomy. While the bladder was open, very careful examination was made, of course, for evidence of any other calculi, and none was found. The one removed was about one and one-fourth inches long, three-fourths inch wide, and one-half inch thick; rounded and smooth, and absolutely without facets. During the convalescence the child contracted pneumonia; the abdominal and bladder wound sloughed and opened up, and there was a small omental prolapse through it. The child finally recovered, and the abdominal wound closed and was sound and firm. A short time afterward symptoms of stone again appeared, and upon searching another one was found. This time, only seven months after the first operation, a median perineal lithotomy was performed and a stone extracted, which was larger than the one formerly removed. It was about one and three-fourths inches long; somewhat cylindrical in shape, with one end rounded, the other cut off square and blunt; and there was a moderate hourglass-like constriction at about the middle. It was rough but showed no facets, and had all the appearance of having been encysted. The interesting question in the case was whether a stone of the size of the second found could have formed in the short time between the first and second operation: or whether it was present at the time of the first operation, and if so where, for it certainly was not in the bladder at that time, that viscus being clear, smooth, and empty, as evidenced by the careful examination of Dr. Judkins and two competent assistants.

Nephrectomy for Cystic Adenoma in a Pregnant Woman.—Dr. Charles L. Scudder, of Boston, reported a case of this nature. At the time of the first examination the patient was nineteen years of age, and gave evidence of an enlarged and movable left kidney with the usual symptoms. About six months later she was married, and soon after became pregnant, during which time the kidney tumor had grown perceptibly larger, and on palpation showed fluctuation. A portion of the fluid was withdrawn with an aspirator, and showed the usual constituents of cystic fluid, with, in addition, however, the rare condition of the presence of bile in it. The kidney was removed without difficulty; it showed no connection by adhesion or otherwise with the liver or gall bladder. The recovery was uneventful; the pregnancy went on to full term, with delivery of a healthy child. The

patient had been well and strong ever since then (it was now three years since operation), and had had a second normal pregnancy and delivery since. Seven days after the removal of the kidney the remaining kidney was secreting a normal amount of urine in the twenty-four hours. The urine was at present about eighteen hundred to two thousand cubic centimetres in quantity in twenty-four hours, of normal specific gravity; the amount of urea was normal; there were at times a very slight trace of albumin and an occasional cast. The interesting points of the case were the presence of bile in a cyst of the kidney, the fact that the operation did not interfere with the pregnancy, and the time that it took the remaining kidney to adjust itself to its double duty.

Hernia Testis.—Dr. G. W. Allen, of Boston, reported a case of this kind. The patient had a long-continued gleet, but had never had syphilis nor any sign of tuberculosis. He had epididymitis for three weeks at time of examination. A little later there was a swelling over the testis, resembling a tuberculous abscess of the epididymis. This was incised, and the incision went directly into the testis. There was sloughing of the skin and adjacent tissues, which persisted for some time. A healing process finally set in, and the tunica albuginea was filled up with granulation tissue. Several attempts were made, unsuccessfully, to cover the raw area with skin. The patient had at present a small area of open granulation, which was slowly closing in. Bacteriological examination of the secretion from the nodule showed staphylococci, but no streptococci, or gonococci, or tubercle bacilli. There was very little suppuration. Dr. Allen thought it unusual to have such a process caused by the staphylococcus.

Third Day—Thursday, May 6th.

An Aid to the Discovery of Tubercle Bacilli in the Urine.—Dr. John P. Bryson, of St. Louis, read the paper. In the past two years Dr. Bryson has noted the possibility of the bladder acting as a reservoir of tubercle bacilli and also the possibility of the bacilli multiplying there, if the conditions present furnish them a good culture medium, *i.e.*, plenty of mucus. The bacilli are not killed by the urine, but for a long time remain in a healthy and active state in the mucus usually found in these bladders. The speaker's method of demonstrating these microbes in the urine consists in having the patient pass voluntarily all the urine that he can. Then he passes a sterile catheter and draws off the residual urine. This may be very small in quantity, perhaps only the catheter full, perhaps only a few drops, but by some pressure on the hypogastrium one can almost invariably get enough to work with. This is caught in a sterile test tube, the catheter being squeezed out if necessary or flushed with sterile water, and then centrifugalized and examined by the usual staining methods. Care must of course be taken to exclude all possibility of contamination from outside sources.

Dr. Bryson detailed a number of instances in which the method had proved of great value, and presented a number of photo-micrographs showing slides from both tidal and catheter urine from the same patient, in which the tidal urine gave few or no bacilli and the catheter urine was full of them.

Oxaluria and Lithæmia.—Dr. Bransford Lewis, of St. Louis, read a paper on "Urinary Inflammations and Disorders, in Connection with Oxaluria and Lithæmia." He remarked that although in most books and monograms on genito-urinary subjects, the general influence of the presence of oxalic acid and uric acid and urates in abnormal quantities was mentioned in a more or less vague way, it being taken for granted that the condition was present, he knew of no systematic literature on the subject. He reported in detail fifteen cases showing the apparent influence of the uric or oxalic acid respectively. In some of the cases almost if not quite all of the symptoms were caused by those acids; in some the inflammatory condition, caused primarily by some other agent, was made much worse by them. He had seen marked frequency of urination, mucous or slightly purulent discharge, even hæmaturia and pain caused by the presence of oxalate-of-calcium crystals in the urine, all of which symptoms disappeared upon proper treatment of the "oxalic condition." He gave as a summary the following conclusions:

1st. Both oxalic and uric acids may appear in the urine either in a physiological or a pathological manner.

2d. When pathological, they may exert certain injurious effects upon the genito-urinary organs.

3d. These effects may be either the inciting of disease where there has been previous health, or they may act by rendering more serious and resistant to ordinary methods of treatment other inflammations and disorders of those organs which are already present (*e.g.*, gonorrhœa, etc.).

4th. The uric-acid element is not always frankly evident as a causal or complicating factor in such cases, and

5th. When recognized is neither more nor less easily controlled than when its disease manifestations occur in other organs of the body.

6th. When either the oxalic or uric acid element is acting injuriously in the way mentioned, systemic treatment (dietary, hygienic, and medicinal) is demanded, and may even take precedence over the local measures that are usually considered sufficient in such inflammations and disorders.

For medication he had used mostly citrate of lithium and the salicylates in some form. The diet was carefully regulated, and if the oxalates were present in abundance he gave plenty of meat and no vegetables; if the urates or uric acid, he gave vegetable diet and little or no meat. The local treatment was that usually adopted for the inflammatory condition which was present, according to its cause and stage, etc.

Dr. White said that he had been in the habit of regarding these disorders as always associated with neurotic conditions. He related one case in which sexual failure had been connected with oxaluria, and stated that with relief of the oxaluria by appropriate treatment the sexual difficulty had disappeared. He had almost altogether given up the use of the salicylates directly, but was in the habit of using combinations of caffeine, phenacetin, and salol.

Dr. Bangs spoke of the important relation existing between the processes of animal chemistry within the body and the urinary tract. Systemic and hygienic treatment he did not believe was enough; he thought that in many if not all cases one would have to give considerable local treatment, just as when these diathetic conditions were not present.

Dr. Watson referred to the undoubted existence of cases of gouty urethritis, in which there were large quantities of uric acid and urates, with bladder irritation and sometimes a purulent discharge, and mentioned the relation between these conditions and hæmaturia occurring before the formation of stone. In the cases that he had seen, the persistency and obstinacy of the condition had been very marked, often resisting for long periods every known method of treatment, local and systemic.

Dr. Bryson had observed often that the uric and oxalic diatheses had increased inflammatory conditions already existing, but thought there would be

no actual purulent discharge without some other infection being present. He had never made out any satisfactory relation between these diatheses and sexual irregularities.

Photographing the Interior of the Bladder.—Dr. William K. Otis, of New York, showed an instrument for this purpose. It was a Nitze cystoscopic tube with a small circular camera, or rather plateholder, attached to the proximal end. There was a small "finder" attached above the plateholder, into which the image was thrown by right-angled reflecting prisms. The best exposure time with ordinary plates he had found to be about fifteen or twenty seconds. By rotation of the circular sensitive plate ten pictures could be taken without changing the plate. Dr. Otis objected to and criticised the circular plate, as it was difficult to cut the round glass plates well, and inconvenient to cut out the individual photographs from the printed picture. He was now having an instrument made that would take a square plate, which he thought would be much easier to manage in many ways. He spoke of an earlier instrument of Fenwick's, in which the effort was made to take a larger picture than was practicable. This instrument, which he presented, takes the picture just the actual size of the calibre of the tube, which can then be enlarged from the original negative. He showed no pictures.

The association then adjourned to meet next at West Point.

AMERICAN MEDICAL ASSOCIATION.

SECTION ON PRACTICE OF MEDICINE.

J. H. Musser, M.D., Philadelphia, Chairman.

Tuesday, June 1.

Address of Welcome.—Dr. J. H. Musser, chairman, made a brief address of welcome, and also read a paper on "The Treatment of Dilatation of the Heart" by title. Dr. Musser said: "If you recall the foundation of the city which has the honor of entertaining the American Medical Association this week, the city of justice and love; if you remember that you are in the city of the minimum of tenements, the maximum of homes, exhaling an air of hospitality, you need not be reminded that its citizens vie with one another in extending you a hearty welcome. Recall the fact that in this community labored Rush, Morton, and other distinguished physicians; that here the first hospital of the country, the first medical school, the first public library were founded; that here the first academy of natural science, the first medical society (the College of Physicians), the first scientific body (the American Physiological Society), were organized, and you cannot but feel that in this city of brotherly love you are thrice welcome."

The Schott Treatment of Cardiac Disease.—Dr. W. B. Carnac, of Baltimore, read the paper. The first part described the bath and exercise systems employed by Schott at Bad Nauheim, and Schott's theory of the action of the saline baths. The author's principal object was to state results obtained from the same system, but with the use of artificial baths, at the Johns Hopkins Hospital, Baltimore. The number of cases was yet limited, ten—all of chronic cardiac disease. The principal effects noted were: (1) Marked influence upon the position of the apex beat, bringing it from the left toward the median line and its normal position; (2) increase in the amount of urine; (3) very marked improvement in the pulse, even in cardiac dilatation associated with arterio-sclerosis; (4) the inefficiency of the treatment in extreme nephritis. Of the ten patients, four died, two showed no improvement, one showed improvement only during the treatment, three had continued to improve. It was remarked that no one claimed to cure chronic cardiac disease. In one fatal case (fatal quite independently of the treatment) there was aortic insufficiency, in two there were dilatation and arterio-sclerosis, in one there was chronic nephritis, in one mitral stenosis. The author concluded from this limited experience that extensive nephritis was a serious obstacle to success with the baths and exercise, though if it was not too grave the patients might be benefited. Extensive changes in the position of the apex beat and cardiac outline did not necessarily indicate permanent good results. Arterial sclerosis did not necessarily contraindicate the treatment. Among drugs, digitalis was freely employed in many of the cases. While they had not been able to effect permanent reduction of the size of the heart, they had found in every case slowing and strengthening of the pulse and diminished tension.

Dr. William Osler had seen some patients with whom this treatment had been carried out at Bad Nauheim with rather extraordinary results. To carry it out in either hospital or private practice was somewhat irksome, but it was perfectly feasible.

Dr. Stockton, of Buffalo, referred to the necessity for conducting the exercises with care lest through overexercise more harm than good be done.

Dr. Foster, of Pennsylvania, asked the author whether control experiments had been made with simple water baths.

Dr. Herrick, of Cleveland, thought one ought to inquire into the cause of the heart trouble and the habits of the patient, before deciding upon any course of treatment.

Dr. Morrisy, of New York, spoke of the value which he had derived from massage treatment of chronic heart disease. There was no question in his mind of the benefit of the Schott treatment.

Dr. Jones, of Buffalo, understood that the Schott brothers also directed mountain climbing in suitable cases.

The Prognosis and Therapeutic Indications in Heart Disease.—Dr. D. L. Rochester, of Buffalo, treated this subject in a general way, then gave a few illustrative cases, and stated these general conclusions: In a given case of cardiac disease the prognosis depends chiefly on the condition of the heart muscle and the walls of the arteries, especially the arterioles. The chief therapeutic indications were rest, removal of obstruction to the circulation, massage, baths, regulated exercise, stimulation to rhythmical contraction of the muscular fibres of heart and vessels. Besides carrying out these indications in his illustrative case, he induced mild catharsis by calomel and salines, gave milk and kumyss, and induced diuresis by diuretin. Ordinary measures failed to induce diaphoresis until he combined the administration of pilocarpine and hot baths.

Dr. Herrick, of Chicago, mentioned three cases of cardiac dilatation, apparently due to fibrous myocarditis, the patients entering the hospital with extreme cyanosis, œdema, etc., in which prompt relief followed venesection.

Dr. H. O. West, of Galveston, called attention to two factors acting in the production of cardiac dilatation, viz., continued hydrostatic pressure, the column of blood acting through the incompetent aortic valve upon the cavity of the left ventricle; the second was disturbance of the circulation through the coronary artery in consequence of valvular incompetency. This interfered with the nutrition of the heart muscle. The abstraction of blood was strongly indicated in some cases.

Dr. Marvin, of Louisville, spoke of the great value of strychnine as a cardiac tonic. He preferred to

give it by hypodermic injection, and employed increasing doses, going much higher than one-twentieth grain when necessary.

Dr. J. N. Upshur, of Richmond, had found much benefit from alternate use of strychnine and nitroglycerin.

Dr. Cohn, of Philadelphia, approved of venesection in some conditions of heart disease.

The discussion was also participated in by Drs. Wainwright, J. F. Jenkins, McConnel, Rochester.

Reduplication of the Heart Sounds.—Dr. C. F. Hoover, of Cleveland, read the paper.

The Use of Digitalin with Reference to Dose.—Dr. Henry Beates, of Philadelphia, pointed out in the first part of this paper the reasons which had led him to abandon the use of the crude drug digitalis. The same reasons, complexity of composition and variation in effect, had led him to give up the alkaloid in favor of digitalin (German, pure). This preparation was a derivative from digitalis, uncontaminated by other principles, possessed unvarying strength, was free from that property which produced gastric irritation, was a powerful stimulant of the whole cardiac apparatus, was a reliable and pronounced stimulant of the vasomotor system, did not develop cumulative effects. Dr. Beates gave much larger doses than some had recommended. The minimum dose with him was one-tenth grain; maximum dose, one-third to one-half grain. In all lesions of the heart, with the single exception of mitral regurgitation complicated by dilatation of the auricle, this drug was of great value.

Dr. Fowler expressed appreciation of the practical value of Dr. Beates' paper.

Dr. Herrick, of Cleveland, wished to know whether the author would use digitalin in acute inflammation of the heart. If so, he must differ from him.

Dr. Beates replied that he would not give digitalin in simple inflammation of the heart, but it was valuable in the treatment of the results of such inflammation.

Tracheal Tugging.—Dr. Harry Toulmin, of Philadelphia, read a paper on this subject. His attention had been called to tracheal tugging clinically under Dr. Osler, several years ago, and on looking up the literature he had found it discussed by two authors and mentioned by Dr. Packard. The word tugging meant, as stated by Dr. Ross, more than mere movement; or, if the latter condition were included, the cases might be divided into four groups: (*a*) very slight up-and-down movement; (*b*) slight movement; (*c*) distinct tugging; (*d*) marked tugging. Examination of seventy-five patients with various conditions disclosed distinct tracheal tugging in only seven. The heart was normal in two of the seven, hypertrophied in four, insufficient in one, possibly aortic stenosis was present in another, in one there was aneurism of the ascending aorta. He said he should expect tugging in cases of dilatation of the aorta. If it were safe to draw conclusions from so limited a number of cases examined, he would say: (1) up-and-down movement of the trachea occurs in many healthy individuals, and accompanies other diseases as well as aneurism; (2) in such cases the movement is much affected by respiration, in the majority of cases being present during inspiration only; (3) in a very small percentage of cases distinct tugging of the trachea may be present without involvement of the aorta either by aneurism or simple dilatation.

Thrombosis of the Vessels of the Neck.—Dr. Helen Baldwin, of New York, read the history of a case of thrombosis of the veins of the neck, and gave a *résumé* of thirty-four cases found in literature. Her case was that of a girl who entered the infirmary with a history of having had three attacks of rheumatism, the last one seven years ago. Five days before entering she had swelling of the feet, and afterward swelling in the neck and arm, with pain and such symptoms as attend venous thrombosis. The swelling in the neck was on the left side, along the course of the jugular vein, which was hard, tortuous, and tender, with redness of the overlying skin. There were double aortic and mitral murmurs. The liver was enlarged; there was ascites; albumin and casts were found in the urine. The temperature was persistently low the first five days, from 94° to 96° F., but on taking it by rectum as well as by mouth it was found higher in the rectum, 102° F., and the difference of six or eight degrees persisted. After three weeks double pneumonia developed, the patient died, and autopsy showed cardiac disease, with great dilatation of the right ventricle. The veins of the neck were filled with firm thrombi, and there was evidence of an endophlebitis of long duration in the subclavian vein, which evidently had been the seat of primary formation of the clot. The extension of the clot formation from this point had probably been favored by failing cardiac compensation. Lesions were present in the liver, spleen, stomach, and kidneys.

As to causes, in eight of the thirty-four cases found in literature there was pressure on the veins, causing stasis; in sixteen there was grave blood dyscrasia; in five there was endophlebitis, as in her own case. While the prognosis of venous thrombosis in general was not so grave, in cases involving the jugular veins it had seldom been seen except in the last stages of a fatal disease. Only four of the thirty-four subjects recovered.

Wednesday, June 2d—Morning Session.

Discussion on Orrhodiagnosis of Typhoid Fever.—Dr. William H. Welch, of Baltimore, opened the discussion with verbal remarks on the principles underlying orrhodiagnosis. There could be no question of the great value of any method for positive diagnosis of typhoid fever. While a clinical study of the case was sufficient in many instances, yet there were many cases in which typhoid presented anomalous symptoms, and mistakes in diagnosis were not uncommon. In children typhoid often ran a very irregular course, and in the South it would be desirable to determine how many of the fevers were malarial and how many typhoid, or whether there was a slow climatic fever in the Southern States. A method of positive diagnosis of typhoid fever would aid us greatly. It was a striking fact that before the introduction of sero-diagnosis of typhoid fever the discovery of the typhoid bacillus had led to few practical results, being in contrast with the discovery of the diphtheria and tubercle bacilli. The working out of the method now known as Widal's grew out of investigations regarding immunity, which were undertaken for scientific interest and not for practical application.

Having passed in review the investigations of Pfeiffer, Gruber, Widal, etc., Dr. Welch briefly described the Widal method. The serum of blood of a typhoid patient added to a culture of typhoid bacilli caused the latter to conglomerate and lose their motility. This reaction probably had nothing to do with immunity, or with the bactericidal effects of the blood. Whether the phenomenon was a histological one or a physical one was not known. It (the agglutination) occurred also with dead bacilli. Blood dried for six months, possibly longer, retained almost its full agglutinating power over the bacillus cultures. It was not affected by light, but was destroyed by high temperature—70° to 75° C. The agglutinating property was possessed also by the various juices of the body and serous exudates. Whether it was the same substance which caused both the immobilization and

the clumping had not been determined. The two results were not always present to the same degree.

Regarding methods, Dr. Welch thought the blood should be obtained by pricking the lobule of the ear or finger, a method less likely to beget prejudice than raising a blister or sticking a vein. He also suggested as a point for discussion whether it was best to use serum or dried blood. It had been claimed as an advantage for serum that it permitted greater accuracy in dilution. Perhaps Dr. Johnston, who had brought forward the method of using dried blood, could tell how to make a correct quantitative estimate. The microscopic test was preferred by Dr. Welch to the macroscopic test.

Should one lay most stress upon the immobilization or upon the clumping? All were agreed that young cultures, those which had not grown more than twenty-four hours, should be used. He suggested fifteen hours. Some preferred agar, some bouillon culture. As to the time limit, he would suggest two hours at the temperature of the thermostat. As to dilution, Widal held that one in ten or one in fifteen was best. But in doubtful cases a larger dilution, say one in forty or fifty, would be less likely to show the reaction if the case were not typhoid than if it were. Indeed, no case not typhoid had been positively known to give the reaction with a dilution of one in fifty, while a good many had in dilutions of one in ten up to twenty or twenty-five. Another point of possible error was the presence of the reaction at variable periods in the disease; also for weeks or years after recovery, even seven or ten years.

After mentioning practical results briefly, the speaker said he thought the test was extremely valuable in diagnosis, and local and State health boards ought to establish laboratories to which general practitioners could send specimens for examination.

Dr. Wyatt Johnston, of Montreal, spoke of personal observations and investigations in orrhodiagnosis. He had examined somewhat over six hundred samples of blood, more than half of which were from typhoid cases. He could speak strongly of the diagnostic value of the method. He had experimented by using the clumping of the typhoid bacilli as a means of separating them from others in a liquid culture, filtering this through sand. The colon bacillus ran through, while the typhoid remained clumped. But nothing practical had yet come of the method as it had so far been developed. It had been for the purpose of making the test useful to the general practitioners that he had suggested transmission of dried blood for examination, for Widal had already shown that drying did not interfere with the reaction. In this manner samples to be tested were sent him by post from long distances. The hæmometer enabled him to make a pretty accurate dilution or quantitative test, but he did not advise the method in hospital practice. The clumping took place in a slightly alkaline rather than in an acid culture medium. Dr. Johnston had found the reaction absent in only one case of typhoid, and in that instance the patient was not seen until late in the disease.

Dr. R. C. Cabot, of Boston, read a clinical report on the same subject. Of cases collected in which the Widal test had been applied, in 1,826 supposed to be typhoid the test confirmed the diagnosis in 1,740, or 95.2 per cent. Out of 1,649 cases known to be other than typhoid, the serum reaction was negative in 1,592, or 96.5 per cent. Thus in a total of 3,475 cases the results of the serum test had been borne out by the clinician. Dr. Cabot's own experience related to a little over 400 samples, all tested by himself, from patients seen by him. One hundred and one of these were supposed to be typhoid, and he got the reaction in 96; failed in 5. In 301 known to be other than typhoid, the reaction was absent in 300. In 1 it was positive—a case of pernicious anæmia in a negro. In 17 cases of cerebro-spinal meningitis the reaction was not present. His method was to prick the ear, take a single drop of blood with the medicine dropper, put it directly into a small tube containing ten drops of bouillon culture, and wait fifteen to thirty minutes for the reaction. Unless there were both clumping and cessation of motion, the reaction must be regarded as doubtful.

Dr. W. B. Bloch, of Baltimore, also gave a clinical report on orrhodiagnosis, based on work in the Johns Hopkins Hospital. The serum and dried blood tests had given about the same results. The whole number of tests was 107. Out of 46 typhoid cases the percentage of failures had been 6.5. The method was of value in distinguishing typhoid from some cases of tuberculosis and malaria. In these diseases without complicating typhoid the reaction had been present only in some cases with coma; why it was present then, he was unable to say. He had used a dilution of sixteen; time limit, thirty minutes.

Dr. H. M. Biggs, of New York, sent a paper based on the work of the board of health of New York City. The board at first provided for dried-blood specimens to be sent it by physicians; later it expressed a preference for serum obtained by fly blister, but sometimes used dried blood. Aside from this, the board had seen no reason to change the method originally employed—one to ten bouillon, fifteen minutes. Between three hundred and four hundred samples had been tested. While the serum reaction was by no means specific, yet it was usually reliable. If not applied in a practical way it was liable to lead to false conclusions. The board preferred the lower dilution to the higher, because more errors were likely to arise from the high dilutions failing to reveal typhoid when present than from low dilutions showing the reaction when typhoid was absent. But both could be employed in doubtful cases.

Dr. S. S. Kneass, of Philadelphia, had in the last six months made 103 blood examinations; 45 were submitted with diagnosis of typhoid fever, and 43 of the 45 gave the complete Widal reaction in fifteen or twenty minutes. Cases not typhoid gave uniformly negative results.

Drs. J. H. Musser and John M. Swan, of Philadelphia, presented a paper, which was read by Dr. Swan. One hundred samples of blood had been examined; 35 were supposed to be typhoid, and the reaction was present in 34. Twenty-four were from patients convalescent from typhoid. In 18 of these the reaction was complete, in 4 imperfect, in 3 absent. In part of 7 cases of prior typhoid the reaction was present. In other diseases than typhoid the reaction was absent.

Dr. Mark W. Richardson, of Boston, gave in this paper the results of examinations of 109 stools from 49 individuals, by the Elsner method for detecting typhoid bacilli. Thirteen of the 49 patients were known to have typhoid. In 9 of the 13 the method gave positive result—in 2 of them by the eleventh day, in 7 not later than the twenty-sixth day. In some the bacilli could be isolated only after several examinations. The result was negative in 3 cases. In all 13 the serum reaction was present at least two days before the bacilli could be found, thus showing the superiority of this method. Yet in cases in which the serum reaction was negative or late, it would seem that examination of the stools for the typhoid bacillus would be of value. In 17 stools of non-typhoidal cases all were negative. Twenty-three stools of 13 patients convalescing from typhoid were examined, with 1 positive result.

Dr. N. S. Davis, Jr., said the results of the Widal test in Chicago corresponded closely with those given by Dr. Cabot—over ninety per cent. successful.

Dr. H. O. West, of Galveston, hoped the Widal test would soon be employed more generally by physicians in the South in cases of fever diagnosticated by some as malarial, by some as a climatic continued fever, by others as typhoid.

Dr. Herrick, of Chicago, mentioned two cases of negative Widal test, in which post-mortem showed typhoid and also tuberculosis. These cases raised the question of the influence of the mixed infection on the serum test.

Wednesday, June 2d—Afternoon Session.

Officers.—The nominating committee of the section reported for *Chairman* for the ensuing year, Dr. S. A. Fisk, of Denver; and for *Secretary*, Dr. Albert Jones, of Buffalo. These gentlemen were duly elected.

Observations on Two Examples of Typhoid Meningeal Infection.—Dr. A. P. Ohlmacher, of Cleveland, pointed out the fact in this paper that in very few cases had the typhoid bacillus been discovered as the cause of meningeal inflammation, and it had fallen to him to meet with three cases of typhoid fever in which meningitis was demonstrated. In two of the three, examination revealed the typhoid bacillus as the infecting organism of the meninges. The third case revealed other bacilli as well as the typhoidal in the meninges, and was therefore reported separately as one of mixed infection.

Relapses in Typhoid Fever.—Dr. William Osler spoke upon this subject. The doctor was often erroneously considered responsible for these relapses by relatives of the patient; nor was the diet definitely responsible, unless in a limited number of cases. The term relapse should, he thought, be restricted exclusively to reinfection after a distinct and definite period of apyrexia. Intercurrent relapses, with fall of temperature to nearly normal, did not belong to the same class as true relapse. The sources of reinfection were still unknown. The typhoid bacilli might be present in different organs as well as in the intestine. Out of five hundred cases of typhoid treated in his wards there had been relapse in forty, which was about the percentage given by Liebermeister, and very much larger than that given by Murchison. There might be double, rarely triple, very rarely four or five relapses. In one of his cases the disease with two relapses covered a period of nearly six months. The Brand treatment had nothing to do with relapses.

Perichondritis of the Larynx in Typhoid Fever.—Dr. M. H. Fussell, of Philadelphia, read the paper and showed photographs of a case of perichondritis of the larynx in typhoid fever. The patient had stenosis of the larynx caused by the perichondritis, which Dr. Fussell diagnosticated, but refused tracheotomy. Autopsy showed, among other changes, large perichondriac abscess, necrosis of cartilage. Diagnosis before stenosis was difficult in these cases.

The Rational Antiseptic Treatment of Typhoid Fever.—Dr. H. O. West, of Galveston, Tex., read the paper. There was no drug, or combination of drugs, which had received general acceptance as capable of cutting off typhoid fever. The author gave his reasons for scepticism as to the power of any drug to cut short this disease. It was of infectious nature, and drugs could not reach all of the micro-organisms or kill the germs without killing the patient. The claims for so-called specifics in this disease had not been substantiated by the statistics of others than the promoters of the methods. A rational antiseptic treatment would include liquid diet for several reasons, among them being weakened functional activity of the salivary glands, of muscles of mastication and deglutition, and of the gastro-intestinal tract, more particularly of the stomach. He would reiterate and emphasize the fact that the proper adaptation of the diet to the conditions produced by the disease was far more important than the use of any drug or combination of drugs. Intestinal antisepsis could be promoted by free use of water in the stomach, which tended to wash the organ and to aid digestion. It also stimulated activity of the skin, lungs, and kidneys. For similar reasons the large intestine might occasionally be washed out. Abnormal or decomposing intestinal contents should occasionally be swept out by the cautious administration of a mercurial or saline cathartic. In his opinion the persistent, continuous use of purgatives was bad practice. Before prescribing any of the long list of antiseptic drugs, one would do well to consider the effect upon the stomach. If they favored the development of gases or fermentation, they did harm. His own experience would not add much to the reputation of intestinal antisepsis in typhoid fever. Still, he could recall a few cases in which a good effect seemed to have been produced. There were thymol, bismuth, turpentine, carbolic acid—indeed, the very fact that the list was so long was pretty conclusive proof that none had been found a specific in typhoid. The hygiene of the room required especial attention.

The Treatment of Typhoid Fever.—Dr. J. N. Upshur, of Richmond, Va., was the author. He thought there was a vagueness of conception regarding the treatment of typhoid fever. After mentioning prophylaxis by disinfection of stools, attention to milk and water supply, etc., the author came to the treatment of a case, and placed special emphasis upon perfect rest and quiet in a well-ventilated room with all precautions against spreading infection. The patient must not be left alone, lest in a state of melancholia he commit suicide. Cool water should be given to relieve thirst; the diet should be liquid, easy to digest, nutritious, milk being in general the best food. Implicit directions should be given as to time and quantity in the matter of feeding. No alcohol for young, vigorous subjects; a moderate amount for those accustomed to it. Mild cases required practically no treatment further than rest in bed and observance of the points already mentioned, and the use of enemata if necessary to keep the bowel open. For headache mention was made of cold compress, shutting out the light from the eyes, sodium bromide; for nervous symptoms, musk, valerian, ice cap for a short period. Salol might be indicated for intestinal fermentation; in threatened heart failure, strychnine. For intestinal hemorrhage, turpentine stupe over the abdomen, enemata of ice water, hypodermic of strychnine or ergot, reduced diet; for peritonitis, opium by the mouth. Attention must be paid to the bladder. Regarding abortive treatment, many claims had been made for this, even of a startling nature in the case of the Woodbridge method. Dr. Upshur had never tried it, not because he was prejudiced against it, but because on investigation he had concluded that it had not been supported by the results. He thought the originator of the method must have drawn erroneous conclusions from cases of mistaken diagnosis, having had no death in twelve years, yet having imposed no restriction upon diet or exercise, given no directions as to bathing. In fact, a cure must have taken place frequently before there was time for a diagnosis. The medicine was administered so often as to leave no time for sleep. Was it strange, therefore, that physicians in the great hospitals had not indorsed or commended this treatment? The parasite was more resistant to antiseptic treatment than was the host.

One Hundred Cases of Typhoid Fever.—Dr. H. G. McCormick, of Williamsport, Pa., reported on 124 cases of typhoid fever which he had treated since 1893, the last 100 cases during a period of thirteen months. The first 24 he treated as the professors and

the text-books generally recommended, and 3 of the patients died. Of the last 100 cases he had lost only 1. The one patient died of perforation of the bowel. Of the 100 cases 19 had hemorrhage, some very severe hemorrhage. Principal points in the treatment of the hundred cases were: Milk and animal-broth diet, abandoning anything which disagreed; ventilation; cleanliness; tepid bath twice a day for cleanliness; bowels kept thoroughly open, usually by calomel given every two hours until from four to eight passages had been secured in the twenty-four hours; an occasional enema; water freely by the mouth. He had thus rendered the alimentary canal as nearly aseptic as possible without medicines. He gave every two hours two drops of guaiacol in emulsion. Guaiacol remained as such within the intestine, and thus reached the point at which it was intended to act as an antiseptic. Another point emphasized was that opium ought not to be given in case of hemorrhage. This was against almost universal teaching, but his objection to opium was that it paralyzed the intestine, tympanites developed, the danger of perforation was greatly enhanced. The coal-tar series was dangerous, and was no more effective in reducing temperature than the guaiacol. Strychnine might be given in case a heart stimulant were required.

Dr. William Osler made some remarks in the general discussion of the several papers. Dr. Ohlmacher's case of meningitis with discovery of the typhoid bacillus as the cause in typhoid fever was very interesting and very rare. He had known meningitis to be diagnosticated as a complication of typhoid in many cases, whereas autopsy showed no evidence of meningitis. Regarding Dr. McCormick's remarkable success with one hundred cases of typhoid fever, it was very interesting, but Dr. McCormick was still a young man. It did not mean a great deal to report a number of cases of typhoid without a death. Dr. Osler had had as many as fifty-three consecutive cases without a single death, and Dr. Stewart, in Montreal, had had as many as one hundred and thirty without a death. If by any method of treatment the speaker should have intestinal hemorrhage in nineteen out of one hundred cases, he would want to change his treatment to learn if there was not some method which was less risky. As to diarrhœa, he had observed that the cases which had given the least mortality were the ones in which there was diarrhœa. Opium was indicated in hemorrhage.

Dr. John Cronyn, of Buffalo, had had relapses in four out of sixty-five cases of typhoid the past winter. He asked whether the germ which caused the relapse was in the spleen, or elsewhere, and redeveloped.

Several others spoke, and Dr. Andrews upheld Dr. McCormick, expressing the opinion that if a mode of treatment saved such severe cases of typhoid that in one hundred there were nineteen with intestinal hemorrhage, that treatment was worthy of adoption.

Dr. J. E. Woodbridge, of Cleveland, regretted that he had not been present when his paper on typhoid fever was called for. He had been accused of saying many things which he had not said. He had never said a harsh thing about any member of the medical profession. He was receiving letters constantly from many physicians, giving most flattering results from the treatment with which his name had become associated. Regarding constipation, this was frequently present, and sometimes required saline laxatives aside from the tablets.

The Clinical Symptoms, Bacteriologic Findings, and Post-Mortem Appearances in Cases of Infection of Human Beings with the Bacillus Pyocyaneus.—Dr. L. Bakker, of Baltimore, gave the results of study in this line at the Johns Hopkins Hospital, where it was the custom to make bacteriologic examination in all cases which came to autopsy. They had found the bacillus pyocyaneus at autopsy in various organs of the body, and in some instances also during life in serous collections, etc. The symptoms seemed to be due less to the local action of the bacillus than to systemic poisoning by absorption of the toxins. The bacillus had been found in inflammations of the various serous membranes, also of the mucous membranes, in gangrenous conditions of the skin, etc. One or more organs might be infected at a time. During life the diagnosis of the presence of the bacillus was made by finding it in the urine, by tapping the exudate, by the odor. Less was known about it in chronic than in acute infections. The prognosis was apparently grave, for only fatal cases had been studied, but the writer thought infection by this bacillus was common and the vast majority of the patients recovered. Speaking of treatment, there was already a serum awaiting the clinician's use.

Trichinosis and Trichina Spiralis.—Dr. F. A. Packard, of Philadelphia, read the history of a case of trichinosis in a man, with finding of the trichina spiralis in pieces of muscle taken from each leg. It was the fourth case in which he had made the diagnosis of trichinosis, but the only one in which he had had opportunity to confirm it by seeking for the trichina in the muscles. His patient was still living, the symptoms having largely disappeared. They had in the first place come on rather suddenly while he was at work in the field, not having been ill previously. There were one chill, some vomiting, no diarrhœa, swollen face, œdema of eyelids and surrounding skin, pain in thighs and calves, especially on pressure. The œdema of the face disappeared in four or five days. Profuse sweating for four days; great thirst. Temperature occasionally was 104.4° F., and on several occasions it fell below normal. Excessive leucocytosis was not found. The respiration was rapid. The man had eaten a piece of bologna sausage, but it was doubted whether this was the source of the trouble. The author was inclined to think trichinosis was not infrequent, was mistaken for rheumatic pains in the muscles, and should be looked for also in cases of quick respiration for which there was no other explanation.

Dr. Stockton, of Buffalo, could on looking back over his clinical experience recall cases in which it was likely trichinosis had existed and he had not recognized it. It was probably more common than had been supposed. He would add to suspicious symptoms those of œdema and sweating.

Myxœdema, with Report of Two Cases.—Dr. J. M. Anders, of Philadelphia, reported the cases. The interest in one case was the fact that a diagnosis of chronic nephritis had been made, and urinary phenomena of that disease had been present several years, but after thyroid extract had been taken for six weeks those symptoms disappeared and had not recurred. Photographs were shown of the other case, which was still under treatment. One patient was unable to take the glycerin extract of thyroid without suffering from toxic symptoms, whereas the powdered extract caused no symptoms.

Treatment of Exophthalmic Goitre and Other Vasomotor Ataxias with Preparations of the Thymus Gland and of the Adrenals.—Dr. Solomon Solis-Cohen, of Philadelphia, presented about a dozen patients, and in his remarks referred to former papers setting forth his views of ataxias of the vasomotor system and the etiological bearing of heredity in such instabilities of the nervous system. This hereditary instability could not be wiped out, but contributing causes to such phenomena as sensations of heat, cold, sweating, polyuria, gastric and intestinal disturbances, etc., could be largely controlled by cer-

tain modes of living and by drugs. The cases presented were mostly such as had symptoms pertaining to goitre, with more or less enlargement of the thyroid body and more or less exophthalmia. In these cases he had administered preparations of thymus gland or of the adrenals, and the results had been, in many instances at least, decided reduction in size of the thyroid body and of the protrusion of the eyes. The adrenal preparations had more influence on the circulatory symptoms, not so much on the eye or thyroid as the thymus preparations, but the best results had come from their combined administration.

Plasmodium of Malaria, Illustrated by Lantern Slides.—Dr. J. Daland, of Philadelphia, caused to be thrown on the screen photographic and some diagrammatic pictures of the plasmodium malaria, tertian type, which he had made in some cases under his observation. They showed the red blood cells containing the plasmodium at the various periods of its development and division, and the changes in form undergone by the cell; also a few of the bodies in the plasma outside the cells.

Thursday, June 3d—Morning Session.

Some of the Clinical Uses of the X-Ray in Medicine.—Dr. F. H. Williams, of Boston, read the paper. While he had used the *x*-ray also in surgery, he limited this paper to its uses in medicine, more particularly in diseases within the thorax. During the past year he had examined the chest in five hundred cases, and could say that the method was decidedly useful to the doctor who would take the trouble to examine many chests in both health and disease. In no instance had he seen harm result. Having become familiar with what was the normal brightness of the chest under the fluoroscope, one would find the shadow darker in spots where there were tuberculosis, infarctions, pneumonic consolidation, aneurism, new growths, fluid in the pericardial sac or pleural cavity, etc. The outlines of the heart could be determined, showing presence or absence of hypertrophy, etc. A variation from the normal excursion of the diaphragm was present in pneumonia, pericarditis, and various conditions, and was an important element in diagnosis and prognosis. A gradual return to the normal excursions of the diaphragm took place in pneumonia and some other conditions. In emphysema the shadow was lighter than in the normal chest. Dr. Williams had been able to recognize pneumonia before physical signs could be elicited.

(*To be Continued.*)

The Use of Gauze in the Treatment of Post-Partum Hemorrhage.—Dr. Schaeffer (*Revue Obstét. Internat.*, December 1, 1896) objects to gauze as a material for uterine tampons in case of flooding. There is no danger of sepsis, if impregnated with iodoform or some other antiseptic. If, as often happens, the tampon fails to stimulate uterine contractions, and if, when the bleeding is from a lacerated cervix, the plug does not cause the torn artery to close by thrombosis, the gauze increases the danger, for it acts as a capillary drain and takes up much blood. As the tolerance of hemorrhage is very irregular in different subjects, and an apparently trifling loss will kill certain women, the best rule in flooding is not to allow one drop to be shed that can be saved. Gauze, above all if absorbent, takes up many drops of blood at least. Dr. Schaeffer uses non-absorbent gauze, prepared by impregnating it with gutta percha. It may be mixed with iodoform or airol. By rolling it up into a small ball, it can be passed into the uterus, which it distends without absorbing any more blood. The gutta-percha gauze retains its elasticity, and hence Schaeffer finds it useful in inducing abortion.

Surgical Suggestions.

Tuberculosis of the Superficial Lymphatic Glands.—Dr. Willard (*Annals of Surgery*, vol. xxiv., No. 6) concludes with the following suggestions: 1. Tuberculous infection of superficial glands usually occurs from insignificant wounds, and is most common in the lymphatics of the neck. 2. Infected glands are a constant menace to the system and should be removed. 3. Great caution is necessary in operating on the deeper structures, to prevent injury of vessels or nerves. 4. Excision should be thorough, and repeated operations, if required, are advisable. 5. Improved hygiene, air, and food are essential, in both operative and non-operative cases.

Ununited Fractures: Their Cause and Treatment.—Dr. Patton (*The Hospital*, January 2, 1897) says the causes of non-union are to be classified as general and local. Of the former any acute or wasting diseases, such as syphilis, scurvy, etc., have been held responsible; but it is doubtful to what extent they act and they are certainly of much less moment than the local causes, which are as follows: 1. Wide separation of the fragments, and consequently want of proper apposition; a common example of this occurs in the ordinary transverse fracture of the patella, or fracture of the olecranon, which always unite by fibrous tissue only; (2) interposition of some foreign body between the fragments, such as a piece of muscle or tendon, part of the capsule of a joint, or, in fracture of the lower jaw, a loosened tooth, etc.; (3) imperfect treatment, when sufficient rest is not obtained. This is well seen in cases in which fractures have occurred far from skilled advice and treatment—for example, in sailors at sea. It may, however, occur when splints have been used without properly fixing the fragments, by including the joints above and below the injury, or possibly the circulation may have been interfered with by improper bandaging, but this seems very unlikely, without producing serious damage to soft parts as well. Imperfect fixation is especially likely to occur in oblique fractures of the tibia, the obliquity not only permitting but also aiding in a sliding movement of one fragment on the other, often not easy to prevent; (4) lastly may be grouped together such troubles as possible injury to the blood or nerve supply of the bone at the site of the original accident, disease of the broken ends, such as necrosis, either from constitutional causes or the severity of the injury, or in a compound fracture from extensive suppuration, etc.

Post-Partum Hemorrhage.—Dr. Griffeth, in discussing an article which appeared in *The Hospital Nursing Mirror*, November 28, 1896, concerning the advantages of compressing the aorta, writes as follows: "I used always to be extremely anxious when such cases occurred, or when I was called to them occurring in the hands of others. But having for years practised only this method of treatment in even the very worst cases, and having never, even in one instance, had it fail, I now never think of adopting any other plan. It may be practised at once on the very first appearance of loss at the same time that the uterus is compressed. I have never known it to fail, even in the very worst instances, and, as a rule, the hemorrhage is immediately checked, and quite stopped in fifteen or twenty minutes; nor have I ever after the lapse of half an hour known it to return, though continuous compression had not been kept up that length of time."

Treatment of Retrodeviations of the Uterus.—In simple, uncomplicated retrodeviations, producing symptoms, pessaries should first be employed, to be fol-

lowed, in the event of failure, by Alexander's operation. In movable retrodeviations with healthy appendages but complicated by mild subinvolution endometritis and metritis, Alexander's operation, preceded by curettage, is indicated (curettage and pessaries may cure a limited number of this class). In cases complicated by marked subinvolution endometritis and metritis, or by tubal or ovarian disease, or by adhesions, hysterorrhaphy preceded by curettage is the only method permissible.—Smith, *The Journal of the American Medical Association.*

To Fenestrate a Plaster Splint.—My method is to insert a chip ointment box or other similar article a little larger than the ulcer or wound directly over the affected surface, and with a strip of bandage encircle the limb and box so that the ends of the bandages can overlap and be pinned over the box. Having applied the flannel roller or wadding, I apply the plaster-of-Paris bandages in the ordinary way to the limb, fitting as closely as possible round the sides of the box. When the plaster has hardened I take the pin out of the piece of bandage which kept the box in position, undo the ends and lift up the box, and the ulcer is exposed ready for whatever dressing is required. The rest of the limb is properly encased.—Esler, *British Medical Journal.*

Excision of Testicle.—There is one operation, however, in which I sometimes revert to the old Spence dressing, viz., excision of the testicle. Professor Spence treated this operation wound in much the same way as an amputation. The silk ligatures, which were of course numerous, were brought out at the lower end of the wound, and made an admirable drain. I have often seen in the old days such a wound healed by first intention, all but the point at which the ligatures were hanging out. In my practice, instead of the silk ligatures, I have a strip of iodoform gauze, which can be removed in a day or two.—Miller.

Epithelioma of the Face.—Dr. du Castel has for the last two years treated systematically at a hospital a number of cases of epithelioma according to Darier's method, without occasioning any inconvenience to the patients. This method consists in applying every third day a solution composed of methylene violet, twenty grains, and a drachm each of alcohol and glycerin to the diseased part, and after this treatment a solution of chromic acid (1–5) is substituted for a few days, when a return is made to the methylene violet. The treatment yields the best results when the disease is superficial. When the parts are covered with vegetations the latter should be scraped off to insure penetration of the drug. Collodion is painted on after each application of the drug.—*Medical Press and Circular*, No. 3,003.

Pelvic Pain.—In a paper on dysmenorrhœa, in the *Maritime Medical News*, Dr. Webster says the following points should be remembered: 1. The pain may be directly due to distinct pelvic lesions, sufficient in themselves to produce this symptom. 2. Pain may exist with minor degrees of pelvic trouble, insufficient in themselves to cause more than a small amount of suffering. 3. Pain may be a pelvic symptom in association with some condition which in itself cannot directly produce this symptom. 4. It may be a prominent symptom in cases in which no local changes of any kind can be made out.

Traumatic Hæmarthrosis of the Knee-Joint.—Dr. O'Connor (*New York Medical Journal*, vol. lxiv., No. 21) thus concludes an article on this subject: 1. In cases of effusion into the knee-joint, an aspirating needle should be introduced in order to arrive at a correct diagnosis. 2. If blood is present, an incision should immediately be made into the synovial pouch, and every particle of blood and clot removed; in case of fracture into the joint, the fragments should be examined, and if necessary reduced and fixed. 3. A gauze drain should be inserted for a few days in order to make certain that no further reaccumulation shall take place, and when it is evident that there is no further danger of this occurring the external wound should be closed by "waiting" sutures. When union is sufficiently firm, active movement should be encouraged, and when this can be painlessly executed, then, and then only, is massage a most useful adjunct in restoring the muscles to their normal condition.

Operative Treatment of Urinary Fistula in the Female.—Dr. S. Broido (*Gazette des Hôpitaux*, September 1, 1896) bases the method that he advocates on the two following principles: 1. That the amount of tissue at the site of the fistula is the same after operation as before. 2. That the denuded surfaces are approximated without undue tension upon the edges, and that they are identical anatomically. The method is as follows: The vaginal tissue is elevated at one point with a tenaculum and denuded transversely. Starting at the lower border of the incision, the mucous membrane should be separated along the entire length of the vesico-vaginal septum; the same should be done at the upper border of the incision. Sometimes it is better to construct the upper portion with the aid of a second incision perpendicular to the first, forming two triangular areas with the superior border of the fistula to the division of the septum. These areas should be sutured longitudinally. It is occasionally preferable to form a single quadrilateral denudation superiorly by two ascending incisions which pass transversely. In cases complicated by prolapse of the bladder, if there is difficulty in bringing the edges of the fistula together, it is well to take advantage of the laxness of the bladder walls and to separate the vesical tissue around the edges of the fistulous tract. The sutures are divided into two groups: the vesical, which should be of catgut because they are deep; and the vaginal, which should be of silk because they are more superficial. After the sutures are tied, the bladder should be filled with some fluid, and if any leak is detected more sutures should be put in. The patient is not to be catheterized after the operation.

Antiseptic Value of Iodoform.—Dr. Lombry (*Gaz. Heb.*, No. 7) gives the following as the antiseptic value of iodoform. 1. If in a dog or rabbit wounds infected with cultures of streptococci or staphylococci are powdered over with iodoform they present a better aspect, secrete less, and cicatrize more rapidly than similarly infected wounds left without dressing. 2. The antiseptic action of iodoform is manifest on condition that the experiments are made with culture media dissolving iodoform. 3. Iodoform weakens the virulence of staphylococci and streptococci. It neutralizes or destroys the microbic toxins, but without the neutralization of them or of the bacteria being complete. Instead of having an injurious influence upon the movements and phagocytic properties of the leucocytes, it seems to excite the activity of the latter.

Heredity in Cancer.—Manichon (*Journal de Médecine*) discusses this question, basing his remarks upon his observation of twenty-three families, in which several members were affected. There were 69 cases of cancer in these 23 families, distributed as follows: 57 of the stomach, 4 of the uterus, 3 of the breast, 3 of the rectum, 1 of the bladder, 1 of the liver. Of the 57 instances of the disease occurring in the stomach, 41 were in males, 16 in females. In 11 families the heredity was exclusively in the male line, in 5 in the female; in 6 families both sexes were equally affected.

Out of 22 families 14 showed cancer in the stomach, and of these the males were affected in 8. According to this author, heredity in cancer is no longer doubtful, and he also points out that the special form of cancer is itself hereditary.

Prostatic Disease.—Dr. Dowd, in an article published in the *Buffalo Medical Journal*, February, 1897, says: "Prostatic disease in old men is readily recognized on account of the interference with urination. On the other hand, when occurring in young or middle-aged, it is, in my opinion, rarely recognized, and simply because, instead of abnormal urination, the symptoms are mostly confined to the sexual function, urethral discharge, and pronounced neurasthenia. The function of the prostate, as you all know, is to secrete a fluid for dilution of the semen, it also helping to fill the posterior urethra, thus causing contraction of the perineal muscles, aiding in its ready expulsion. The secretion is slightly acid in reaction. There is one more important use of this fluid, which brings it forward as part of the sexual apparatus. The spermatozoa, until they become mixed with the prostatic fluid, are motionless. This has been demonstrated by Fürbringer, and I have proved the above to be true many times."

To Prevent Hemorrhage.—Dr. Watson Cheyne (*Lancet*), having read Dr. Wright's papers on the value of chloride of calcium in increasing the coagulability of the blood and also of fibrin ferment as a styptic, invited him to superintend the use of these substances during an operation that promised to be very bloody. An hour before the operation a pint of water containing one-half ounce of chloride of calcium was injected into the rectum, and during the operation pledgets of salicylic wool, soaked in Wright's fibrin-ferment solution, were applied to the freshly cut surface. Whether due to this treatment or not, the fact remains that not more than one ounce or one and one-half ounces of blood were lost.

Suppuration of Stitches.—Some writers explain the suppuration of stitches in carefully performed operations by the presence of pathogenic micro-organisms, normally in the underlying layers of the derma, which cause suppuration when exposed to the air. Remlinger states that most of the micro-organisms found in the blood drawn from the fingers come from the lower layers of the skin. We know that flora of the superficial layers is extensive, but he announces that he has found staphylococcus albus twenty-three times, aureus eleven times, and citreus fourteen times, the streptococcus pyogenes eight times, and the coli bacillus five times, in his experiments with blood taken with a sterilized needle from the deeper layers of the skin of fifty healthy men. To avoid error, the needle should not only be sterilized, but should be inserted while red hot. Dr. E. Blondel (*Journal de Méd. de Paris*) says that surgeons might make their incisions with the thermo-cautery, but the same effect can be secured by disinfecting each stitch with alcohol. Dr. Blondel has revived the practice taught by Theodoric and Mondeville, of bathing the wound with wine, and he has invariable success. In total perineorrhaphy, which is so difficult to perform with perfect asepsis, he has secured results far surpassing any previous achievement. He makes as few stitches as possible in the deeper layers, and wets them and the edges of the wound with ninety-per-cent. alcohol, and sponges the tissues with a cotton pad dipped in it. The final suture is sponged with strong alcohol and then dusted with iodoform or equal parts of dermatol and aristol, repeated every second day afterward. Alcohol dries the surface better than any other substance. It has a coagulating effect on the serum, and thus favors cicatrization.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

PARLIAMENT—CARDIAC THROMBUS—DISSECTING ANEURISM OF AORTA — LIGATURING CAROTIDS FOR PHARYNGEAL ABSCESS—IRREDUCIBLE HERNIA—DEATHS OF PROFESSOR CHARTERIS, DR. LAW, DR. GOVER.

London, June 11, 1897.

The report of the departmental committee on dangerous trades (anthrax, etc.) has been presented to both houses of Parliament.

In the Commons the Scotch public-health bill has been reported, with amendments by the law committee. This bill has excited much interest in consequence of an attempt to place sanitary inspectors on a level with medical officers of health—a proposal which is being resisted to the utmost.

A bill to provide calf lymph under government control has been introduced.

The return relating to experiments on living animals in England and Scotland has been circulated.

At the last Clinical Society meeting, Dr. W. Ewart and Dr. H. D. Rolleston gave an account of a case in which a large ante-mortem thrombus was attached to the fossa ovalis in the left auricle, passing through the mitral valve, which was not contracted, into the left ventricle. The patient, a woman of forty-three, after some acute chest trouble, probably pleuro-pneumonia, had the precise symptoms and signs of mitral stenosis with failure of compensation. She ultimately died rather suddenly with symptoms of pulmonary apoplexy. At the post-mortem the viscera showed the usual changes met with in cases of advanced mitral disease, beside which a firm, smooth, dark, hourglass-shaped thrombus was found firmly attached to the lower posterior part of the foramen ovale, passing into the left ventricle, with a constriction at the mitral orifice, which was otherwise healthy. There were no adhesions between the flaps of the valve and the thrombus. Examination of the thrombus showed that it was old internally, and that recent clot had been added to it lately; there was no actual disease of the mitral cusps.

Dr. Kingston Fowler referred to a very similar case formerly under his care, reported by Dr. Voelcher in the Transactions of the Pathological Society, 1893. When found in the auricle clots usually arise between the strands of the musculi pectinati; in the ventricle, between the chordæ tendineæ. In the early stage the central part probably underwent softening, and the cardiac contractions made the clots project as polypi.

Dr. Bertram Hunt then related a case of extensive dissecting aneurisms of the aorta in a woman aged forty-three. While under observation a left-sided hæmothorax developed, and thirty-three ounces of blood were removed by aspiration. A murmur was then heard over the spine. The patient remained in fair health for nine months, when she died suddenly. At the post-mortem a large dissecting aneurism was found, which commenced by an orifice in the inner coat of the aorta just below the origin of the left subclavian artery and opened again into the left common iliac artery. Death was due to leakage into the right lung and pleural cavity. The site of the old leak into the left pleura was closed by adhesions.

Dr. De Havilland Hall said that in his experience, when a large aneurism opened into a serous cavity, there was usually a large sudden escape of blood, whereas when the aneurism ruptured on to a mucous surface the opening was valvular and blood escaped slowly.

Dr. Rolleston referred to two cases of hemorrhage

from the aorta into the pericardium, in which leakage occurred slowly in one, the pericardium was distended with signs of pericarditis, and there was a leakage from an aortic aneurism. In the other there was a very minute opening into the pericardium, which, however, contained twenty-five ounces of fluid. He remembered one case in which Dr. Dickinson diagnosed a dissecting aneurism during life, from the very acute pain which radiated along the arteries in both arms and legs.

Dr. Ewart agreed that gradual leakage sometimes occurred in cases of rupture of an intrapericardial aneurism.

In addition to his paper before the Medico-Chirurgical Society, reported in my last, Mr. Clutton read an account of a case of pharyngeal abscess followed by very severe hemorrhage from an abscess in the roof of the pharynx above the right tonsil, which was eventually successfully arrested by the ligature of the common external and internal carotid arteries. The abscess cavity was at first plugged with cyanide gauze, as it was thought the bleeding might be from the internal jugular vein; but later it was clearly from a large artery, probably the internal carotid. The bifurcation of the common carotid on the right side was exposed, and a goldbeater's skin ligature applied by means of a "stayknot" to the common carotid and its two branches. Considering the difficulties in determining the exact source of hemorrhage when it occurred from a pharyngeal abscess, Mr. Clutton believed it to be the safest practice to tie both the external and internal carotid arteries, as well as the common carotid, for all three arteries were reached through the same incision at the bifurcation. The necessity for tying two of them had been shown by Mr. Pitts' paper in the St. Thomas' Hospital Reports, vol. xii., and the addition of the third scarcely increased the length of the operation. Mr. Pitts referred to a case in which ligature of the common carotid artery was hastily performed, and twenty-four hours later profuse hemorrhage recurred and proved rapidly fatal. The source of hemorrhage had proved to be the internal carotid, and he had been led from his experience in this case to insist on the ligature of at least the common and external carotid arteries in such a case.

Mr. Harrison Cripps had collected sixty-eight cases of ligature of the common carotid, and had been struck with the high mortality, largely from brain symptoms, occurring immediately or in a few days, or from secondary hemorrhage; so that ligature of the common carotid was a very formidable operation. Out of all the cases there was clear evidence only in one that the internal carotid was the source of the hemorrhage, and when that occurred death would probably take place at once, so that the question of operation did not arise. He thought that in most cases ligature of the external arotid would suffice, and was much less dangerous than ligature of the common trunk.

Mr. Warrington Haward read a paper on "Irreducible Hernia," based upon an analysis of eighty-five cases in which an operation was performed for irreducible hernia. His conclusions were: 1. Irreducible hernia is a condition of serious danger, the gravity of which increases with its duration or neglect. 2. The application of a truss upon an irreducible hernia is not only useless but harmful. 3. Irreducible herniæ which consist wholly or in part of bowel are very apt to become strangulated. 4. Herniæ consisting wholly of bowel, upon which no truss has been worn, may (even when of large size and of considerable duration) generally be returned by appropriate treatment. 5. Of the cases of hernia in which proper treatment fails to obtain reduction, the great majority are irreducible because of adhesions of or changes in the protruded viscera—conditions which are remediable only by operation. 6. The most common cause of irreducibility is the presence in the sac of adherent omentum. 7. The presence of irreducible omentum in the sac of a hernia is a source of constant danger, which can, nevertheless, be remedied by an operation of extremely small risk. 8. Herniæ containing irreducible bowel are more dangerous than those containing only omentum, and as the danger of operation increases with the magnitude of the hernia and with the occurrence of adhesions, these herniæ should be operated upon as soon as they are proved by the failure of proper treatment to be irreducible.

Mr. A. E. Barker indorsed all the conclusions at which Mr. Haward had arrived; but Mr. Macready made light of the pressure of a truss causing adhesions; on the contrary, he held that it favored the absorption of adhesions.

Professor Charteris, of Glasgow, died on Monday, at Comrie, Perthshire. He had gone there to recuperate after influenza. His health had been failing for some time, and he was unable to give his course on materia medica and therapeutics this session. His "Student's Guide to the Practice of Medicine" is probably well known to you. His contributions included important researches on the salicylates and on carbolic acid. His recommendation of chlorobrom in seasickness excited a good deal of attention some three years ago. He was also the author of a work on health resorts, and wrote the article on that subject in Quain's Dictionary.

Dr. Joseph Law, consulting physician to the Sheffield Royal Infirmary, with which hospital he was connected over fifty years, died on the 1st inst., at the age of ninety.

Dr. R. M. Gover, late Her Majesty's inspector of prisons, died on the 5th. He retired on account of failing health last December. He was a valuable officer, and his reports contain important observations and suggestions. His consideration for others secured him the esteem and regard of the staff of the prisons.

"CRIMINAL ABORTION."

To the Editor of the Medical Record.

Sir: In your issue of May 22d, Dr. T. F. Connelly criticises Dr. H. P. Beirne's article on "Criminal Abortion." No doubt in the rural districts most women are lacking in the knowledge of how to procure an abortion. Unfortunately it is too true that in the cities abortions are performed scientifically by a large number of women without any aid from a physician. Scores of women are able to find the "mouth of the womb" with greater facility than a recent graduate, and have no difficulty in passing a catheter into the uterus. Most American wives look on pregnancy as a domestic calamity, and no amount of advice on the enormity of the sin or on their responsibility to Almighty God will deter them from what they believe to be the exercise of woman's rights. Why is it that more children are born of foreign-born mothers than of American-born women? How is it that the average American family consists of two or three children? It is not until the foreign-born woman is initiated into the art of murdering her offspring that she ceases to populate the country. I know one woman who can procure an abortion by packing her vagina with warm, moist, fine-cut chewing tobacco and squatting over a vessel containing hot water. There is no crime so base, nor any which so cries to heaven for vengeance, as the murder of the innocents. It is possible to make atonement for other crimes, but for murder restitution is impossible.

E. T. Milligan, M.D.

Detroit, Mich.

To the Editor of the Medical Record.

Sir: I beg leave to differ from Dr. Conolly, who takes the position in your issue of May 22d that women practically never produce abortion upon themselves either with medicines or instruments, for the simple reason that they cannot. My experience teaches me that women do know how to produce abortions upon themselves, both by instruments introduced into the uterus and by taking violent medicines internally; and that in cases too numerous to mention they resort to these criminal practices, with dire results many times. Of course it cannot be denied that most produced abortions are brought about by unscrupulous people who have had some medical training; still we ought not to be blind to the great harm done by women upon themselves, and one woman can spoil a good many others in her vicinity.

W. O. Henry, M.D.,

Omaha, Neb.

"DON'T TRUST YOURSELF IN THE HANDS OF THOSE COUNTRY DOCTORS."

To the Editor of the Medical Record.

Sir: A few months ago I was called to see a patient, thirty-eight years of age, who was nearly bedridden as the result of spinal neurasthenia and a typical retroflexion of the uterus. The patient had previously undergone four months' treatment in a sanatorium, at a cost of several hundred dollars. The only thing that had been done for her was to subject her to electrolysis according to Apostoli's method, and return her to her friends with the assurance that her case was practically cured, and that a few weeks would suffice fully to restore her strength and convince them of the great value of the treatment to which she had been subjected.

The physician who had charge of this case is a gynæcologist of national repute, and as a part of his final advice to the patient, he said: "Don't trust yourself in the hands of those country doctors. If you do not progress satisfactorily, write me and I will advise what course to pursue," etc.

The patient and friends waited very patiently for the improvement which never came, and after a few weeks one of those maligned "country doctors" saw her and on examination found that she still retained the retroflexion in its original form and the neurasthenia was worse, if anything, than before she had undergone treatment. Sequelæ: Eminent specialist, richer in fees but with the loss of some reputation, drops out. Patient, rich in experience but poorer in purse, at the instance of a "country doctor" submits to operation and is relieved of the retroflexion and under rest and appropriate treatment is slowly regaining the lost nerve tone.

Instances without number could be cited to show the aggressive tendencies of the physicians in our cities toward "the ignorant and benighted country practitioner," as the urban physician is prone to call his country brother; but the one given will suffice as a good illustration of the fallacy of the position which the physicians of the city have assumed toward their fellows in the rural districts. That the attitude of the former is based upon a fancied rather than an actual superiority, is apparent to those members of our profession who have had a wide experience in both city and country practice, and who in consequence of such experience are best qualified to pass upon the merits of the two classes mentioned. Such judges as these invariably tell us that the country physicians have as a rule better professional attainments than those of the city, and that it is only a few of the many who reside in the city that can claim with any show of justice their right to superior professional attainment.

The country physician who rode several miles upon a dark night to a patient suffering from strangulated hernia, which he relieved by cutting with the meagre instruments from his pocket case, and saved his patient, is a hero when compared with the mediocre city physician who lost a similar case through lack of skill and promptness of action, and the delay occasioned by the calling in of one who was qualified to operate.

The country physician is too apt to entertain invidious feelings toward his fellow competitor, but toward his city brother he evinces feelings of respect which too many times is very poorly reciprocated. Neither is the country physician resentful, as much as he should be, of the aggressive and intrusive tendencies on the part of his urban neighbor. Too often the latter when meeting the former assumes a kind of dictatorship in affairs; and this happens many times, too, when the true situation has not been grasped by the would-be dictator, who more than occasionally fails to discover the real condition of the patient, notwithstanding his self-assumed and erudite air of superiority.

Again it is quite a common practice with city physicians to fill their *clientèle* who spend their summers in the country with the idea embodied in the above title: "Don't trust yourself in the hands of those country doctors." This they do ostensibly for the welfare of those under their charge, but in reality the true motive is to maintain their hold upon their patrons even while absent on their vacations. How to overcome the distrust thus created in a patient may be a difficult problem. The proper way is for the country doctor to maintain his dignity and self-possession, and to act with promptitude. He can be kind yet firm, and withal he should insist upon his plan of treatment being faithfully carried out without undue deference to the notions that the patient or his friends may have respecting the treatment. If the family doctor from the city is called into the case, meet him courteously and in a strictly ethical way. If he is obtrusive and tries to create distrust in you, insist upon your rights, and if you cannot obtain them withdraw from the case. If the country doctor would follow this advice, the evil complained of would soon be a thing of the past.

There is no good reason why the city physician should be aggressively inclined toward his fellow practitioner in the country, and he will not exhibit his aggressive tendencies if the latter exacts a respectful consideration of his rights and privileges.

In conclusion I have to say, let it be known that in the country many "a practitioner of the old school" still lives and is as worthy of praise and honor as in days of yore, and respect and proper recognition will not be withheld from him even by our city brethren.

A. Llewellyn Hall, M.D.

Fair Haven, N. Y., June 5, 1897.

MILK CONTAMINATION.

To the Editor of the Medical Record.

Sir: The great importance of a pure milk supply to a great city like this needs no comment. Much has been said by physicians and not a little has been done by the authorities toward insuring consumers a proper quality of milk. Tuberculous cows are now pretty generally discovered and destroyed. I wish to call attention briefly to a possible source of tuberculous as well as other contamination which should be corrected. I refer to the danger from infected milk bottles. Every physician of wide experience in this city must have had it happen in his practice, as it has happened in mine many times, and always with protest, that patients bring urine, pathological specimens, and sputum in milk and especially in cream bottles. The order given

to procure a wide-mouthed bottle seems to suggest at once to a certain class of patients that it is better and cheaper to take one belonging to the milkman than to buy one at the drugstore. The physician cannot make sure that the bottle is destroyed, there is always a possibility of its finding its way back into some milk dealer's hands, and the public has no assurance that his methods of cleansing and sterilization are perfect and reliable. A law is called

for to prevent the use of beer, wine, or milk bottles which can by any possibility be used again for food or drink-holding purposes from being used in any such way. The above cut, showing a fœtus mummy in the bottom of a cream jar recently brought to my office, illustrates the points I have tried to make. Fancy the unappetizing effect of consuming milk from such a bottle as this and finding a dried fœtus as a sediment.

CHARLES W. ALLEN, M.D.

126 EAST SIXTIETH STREET,
May 27, 1897.

Therapeutic Hints.

Roentgen Rays were utilized by Dr. Leopold Freund to destroy a hairy nævus occupying the neck, shoulders, and lateral portions of the thorax in a young boy. Kaposi thought that when the nutrition disturbances which had been set up had disappeared, the hairs might grow again.

[In all instances of accidental alopecia caused by the *x*-rays so far reported, the hair has shown a tendency to grow again, and for this reason in a recent editorial we ventured the opinion that the rays could not be successfully employed for purposes of epilation.—ED.]

Gargle in scarlet fever, measles, etc. The following is useful in the subacute inflammatory affections occurring during the course of the exanthemata:

℞ Acidi acetici	ʒ ij.
Glycerini	ʒ i.
Aquæ	ad ʒ viij.

Burow's Liquid, prepared according to his own formula, calls for:

1. ℞ Plumbi acet. cryst.	100
Aq. distil	300
2. ℞ Alum	66
Sod. sulphat.	12
Aq. dest	500

Mix the two solutions cold, and let stand for two days at a temperature less than 10° C. Filter without washing the precipitate. There should then be no trace of lead in the solution, which can be applied to extensive raw surfaces without the danger of lead poisoning, which is not the case when the solution is improperly prepared.—*Le Scalpel.*

The Treatment of Syphilis by Intravenous Injections of Mercury.—Dr. Ernest Lane (*British Medical Journal*, December 12, 1896) summarizes the advantages of this method of treatment as follows: 1. The injections are absolutely painless, which is an advantage over the intramuscular method. 2. The functions of the digestive tract are not interfered with. 3. The doses of the mercurial salt, being small, can be easily regulated to suit the varying susceptibility of different individuals. 4. With ordinary precautions the treatment is perfectly safe; even if the vein is missed, little or no inconvenience is felt. 5. The resulting improvement is certain and rapid, and consequently the method seems to be indicated in cases of cerebral syphilis. Dr. Lane is not able to say whether or not this treatment is followed by relapse. The only real difficulty is the trouble experienced in some instances of bringing the veins into sufficient prominence. This is an insuperable obstacle; still he thinks that in intravenous injections we have a valuable addition to our means of applying antisyphilitic therapeutical agents, though one he cannot recommend as a routine practice.

The Administration of Quinine to Children.—1. Quinine pearls, gelatine capsules containing one and one-half grains, are taken readily by children over three years of age, while younger children can be taught to swallow them. 2. Quinine chocolate, each piece containing one and one-half grains, the bitter taste so well covered that infants of nine months take them, and they do not produce gastric disturbance. 3. Suppositories made of cacao butter, and containing various doses up to seven and one-half grains. 4. A hypodermic solution of one part of hydrochlorate of quinine in four parts of water. With proper precautions the injections are not followed by abscesses, and are found valuable in cases of whooping-cough in which quinine could not be tolerated by the mouth. 5. Quinine may be given in enema; the quantity of solution used should not exceed one ounce. 6. Tannate of quinine, which in powder is almost tasteless, is a fairly satisfactory substitute for other preparations, but the dose given must be double that of the sulphate, and the effect is not produced so rapidly nor so certainly.—BINZ, *Deut. med. Woch.*

Treatment of Eclampsia.—Dr. Charpentier believes he is authorized to submit the following as the conclusions of his investigation of the subject: 1. Every pregnant woman with albumin in her urine being exposed to attacks of eclampsia, the milk diet giving splendid results against the albuminuria, and in particular that met with in pregnancy, the urine of pregnant women should be examined with the greatest care, and, if albumin is found, no matter how small it may be in quantity, an absolute and exclusive milk diet should be instituted. This is the preventive treatment *par excellence* of eclampsia. In cases in which œdema is present without albuminuria, it is well, if not an absolute necessity, to prescribe the milk diet. 2. Every time we find ourselves in presence of an eclampsia, begin, if the patient is strong and vigorous and if cyanosis is present, by a bleeding of from two hundred to three hundred grams, and then give chloral; give milk by the mouth and, if necessary, through a sound. 3. Combat the attacks themselves by inhalations of chloroform and favor diuresis by subcutaneous injections of artificial serum. 4. If the woman is delicate, the cyanosis is not very marked, the attacks are not very frequent, chloral should alone be given. 5. Wait until the labor occurs spontaneously

and allow it to end without intervention whenever this is possible. 6. If labor comes on spontaneously, but does not end, because the uterine contractions are too feeble or too slow, end the labor by the application of the forceps or a version, followed by extraction, if the child is living, or by a cephalotripsy, basiatripsy, or cranioclasy, if the child is dead. 7. Before an intervention wait until there is complete dilatation, or at least a dilatability of the cervix, in order that the operation may be done without violence, and consequently without danger for the mother. 8. Reserve induced labor for a few exceptional cases. 9. Reject, absolutely reject the Cæsarean operation and *accouchement forcé* as current methods in the treatment of eclampsia.—*Annals of Gynæc. and Pæd.*, January, 1897.

New Instruments.

A NEW ELECTRIC HEATING PAD.

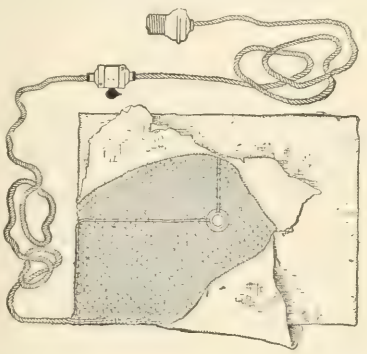
One of the facts early noticed in electrical experimentation was the heating effect produced by the passage of a current through a wire. This manifestation has since been utilized in many practical forms, among the most familiar of which, hailed in times past as most useful discoveries, are the heating to incandescence of the filament in the incandescent lamp, the localization and control of the required temperature of the wire in the cauterizer, and the production of useful heating apparatuses. When used for cooking the extreme effects of the current are neither expected nor required, the purpose being economically to utilize the heating effect in the production of temperatures within given limits and always under control. The modern physician, with his battery and electro-medical cabinet, undoubtedly stands nearest to the professed electrician in his knowledge of the behavior and effects of electricity. It is not surprising, therefore, that he should be among the first to appreciate the improvements being made from time to time in apparatuses which claim his interest as offering some new means whereby improved results may be obtained by the applications of simpler methods. This last remark is made with more especial reference to the adoption by physicians of the electric heating pad, which promises to occupy as secure a position among his modern appliances as the cauterizer or ozone generator.

The electric heating pad offers advantages and benefits not readily obtainable with the hot-water bottle and similar means for making local applications of heat. The proper management of the hot-water bottle requires a watchful care and frequent renewals to obtain the desired effect, and necessitates repeated agitation of the patient and periodical extremes of temperature with the risk of exposure incidental to the constant changes; or, as in hospital practice, it involves elaborate and bulky circulating apparatus, both troublesome and expensive. The facility with which connections may be made with the electric current, and the simplicity and utility of the heating pad as a practical substitute for cruder methods, have already led to its adoption in various institutions and in household practice.

Unlike hot-water applications, which cool rapidly, the electric heating pad receives a constant and uniform supply of heat; and by simple means it is possible to maintain or regulate the temperature as may be desired without unnecessary disturbance of the patient. The electrical method offers a further advantage in that the temperature may be raised gently and the patient spared the discomfort and the shock of the sudden application of the hot-water bag at its highest temperature. The gradually increasing temperature of the pad, or its prolonged application at a fixed temperature, also assures the deeper penetration of the heat and the attainment of more thorough therapeutic effects. In pneumonia, cramp, rheumatism, and other cases in which the maintenance of a suitable temperature may be of vital necessity, it is apparent that any means, which, with corresponding advantages, would prolong a given temperature indefinitely, must be of the highest value. In the treatment of inflammatory affections of the pelvis, both acute and chronic, in peritonitis, and in ovarian neuralgia, the heating pad is likely to prove efficacious.

The weight of the water bottle not infrequently offers objections to its use in the treatment of diseases of the stomach, bowels, and other organs, when the parts are sensitive to compression.

The construction of the electric heating pad is illustrated herewith. The conductor forming the resistance or heating wire, is covered, and is thus thoroughly insulated and protected by asbestos. It is then woven into a cloth or pad about eleven by fifteen inches, and one-fourth of an inch thick. The arrangement of the circuits is such that by means of a simple



regulating switch, shown in the lamp cord, three degrees of heat may be obtained by manipulating the key. The cord attached to the pad is provided at its end with a connecting plug for attachment to the ordinary incandescent lamp or wall socket. The full amount of electric energy required to heat the pad is the same as that for a sixteen-candle-power lamp, namely, about $\frac{6}{10}$ of an ampere on a 110 volt circuit. The regulator is marked with the four positions of the key, 0, 1, 2, 3. At 0 the current is turned off; at 1 about $\frac{2}{10}$ of an ampere will flow; at 2, $\frac{4}{10}$; and at 3, $\frac{6}{10}$. To heat the pad quickly, the key is first turned to 3. The pad will soon attain a working temperature, and its subsequent behavior may be readily regulated to any degree by turning the key in the switch to 2, to 1, or to 0, as may be necessary, or by the judicious arrangement of coverings.

The effect of the latter upon the rapidity and intensity of the heating will be apparent. The pad receives a constant supply of heat from the electric source. If this heat be permitted to escape by freely exposing the surfaces of the pad to the air, no great effect will be apparent in the pad itself—in other words, it will not get hot. If, however, the pad be confined between coverings of any description, whether it be blankets or the human body, so as to prevent the escape of the heat, the latter, being supplied constantly, will accumulate until a temperature is attained which may be excessive for therapeutic purposes; and, were it not for automatic means of control within the pad itself, there would be the ultimate risk of the temperature

becoming unnecessarily severe for both the patient and his surroundings. By the introduction, however, of the thermostat or temperature regulator, shown in the shape of a button situated in the centre of the pad, any such danger is practically obviated.

When applied to the skin, 213° F. is an unendurable temperature; and it is not to be taken for granted that in the form of a heating pad such a temperature is recommended or is desirable for ordinary applications. But, to meet average conditions, the setting of the thermostat at such a limit—the thermostat is to be regarded always as a safety valve—has been found to furnish temperatures suitable and convenient for the usual applications. The exposure of the heating pad, whether altogether or in part, is so influential in determining the ultimate temperature under a given set of conditions, that if the thermostat be caused to work—that is, to limit the heating, say, to 165° F.—there is an immediate complaint from the average user that the pad does not get hot enough. It would appear perfectly practicable to construct the heating pad for special conditions and to render it of the greatest value in the treatment of numerous special cases.

The interposition of coverings between the body and the pad, whether they be used as a poultice, an embrocation, or shield, can modify temperature accordingly.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending June 26, 1897:

	Cases.	Deaths.
Tuberculosis	151	111
Typhoid fever	10	8
Scarlet fever	185	16
Cerebro-spinal meningitis	3	6
Measles	227	8
Diphtheria	265	27
Laryngeal diphtheria (croup)	9	9
Chicken-pox	13	9

At Home.—The Doctor—"Mrs. Brown has sent for me to go and see her boy, and I must go at once." His Wife—"What is the matter with the boy?" The Doctor—"I don't know; but Mrs. Brown has a book on 'What to Do Before the Doctor Comes,' and I must hurry up before she does it."

Thymic Asthma.—The diagnosis of this disease is usually made after the death of the patient. In the case of a child described recently, who suffered from intense dyspnœa, tracheotomy was performed without result, and it was decided that the cause must be some compression by a tumor or hypertrophied thymus gland. Extending the incision, the thymus gland was found extremely enlarged and was removed. At once the respiration became normal, and the child was completely cured. Siegel, who reports the case, suggests that it would be more appropriate to designate this trouble as thymic stenosis of the trachea or bronchi.

Another "Human Ostrich."—A Kansas city street fakir, whose special means of entertaining an intelligent public was to swallow any and everything, recently found his stomach becoming too full, and was obliged to have it opened. The surgeon who performed the operation removed, according to the newspaper report, the following articles: One four-bladed knife, one and one-half inches long; one two-bladed Barlow knife, four inches long; one knife blade, three and one-fourth inches long; one knife blade, three inches long; two knife blades, each two inches long; one knife blade, one inch long; thirty-two eight and ten penny fence nails and spikes; thirty-four sixpenny wire nails, sharp pointed; twenty-six shingle nails, each one inch long; sixteen carpet tacks and small wire nails, one horseshoe nail, three large screws, one barbed-wire staple, and three ounces of fine glass.

Vital Statistics of Philadelphia.—For the week ending June 19th, there occurred in the city of Philadelphia 394 deaths—11 more than during the preceding week, and 20 less than during the corresponding week of the previous year. Of this number, 162 occurred in children under the age of five years. The largest individual causes of death were as follows: Pulmonary tuberculosis, 45; pneumonia, 31; heart disease, 20; diphtheria and carcinoma, each 19. There were reported during the week 119 cases of diphtheria, 79 of scarlet fever, and 39 of typhoid fever, as compared with 96 of diphtheria, 124 of scarlet fever, and 74 of typhoid fever during the previous week.

The Specialist of To-day is essentially a self-made man, there being no method of insuring the possession of special skill nor any legal or professional restrictions upon any one who chooses to announce himself as a specialist. Thus, so far as a specialty is concerned, the physician at the present time is as free from college or society supervision and as innocent of a diploma as might have been the general practitioner of several centuries ago. Under these circumstances a man who calls himself a specialist cannot be considered as claiming superiority over his professional brethren, but merely as one who seeks to limit his practice from financial motives or because he is conscious of certain proclivities and interests.—*Medical and Surgical Reporter.*

Ricord used to say, concerning the preparations of gold that certain practitioners had substituted for mercury as specifics in syphilitic diseases, that, everything else being equal, they produced better results when administered by the patient to the doctor than by the physician to the patient.

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ending June 26, 1897:

		Cases.	Deaths.

THE APPENDIX IN THE INTERVAL.—A NEW METHOD OF STUDYING IT.

BY ROBERT ABBE, M.D.

WHEN a surgeon has removed an appendix in the interval between attacks, he usually studies it, either by immersing it in alcohol and submitting it to section after days of hardening, or he makes as careful an examination of the fresh specimen as he can by trying to pass a probe into it to detect stricture, or slicing it from end to end. Either method gives little or no idea of its pathological condition.

During the past few months I have adopted another method, which has revealed a most unexpected and perfect demonstration of the exact pathology of its diseased structure and which virtually shows the causes of appendicitis in its several varieties, and demonstrates to the eye that which gives an explanation of the clinical symptoms of chronic cases.

Within a few hours after removal the appendix should be distended with ninety-five-per-cent. alcohol, through a conical nozzle of a small syringe tied tightly into its cut end by a ligature, which is tightened as the syringe is withdrawn (Fig. 1). The distended organ is then immersed twenty-four hours or more in alcohol of the same strength. It is then ready for section. If it is sliced centrally from end to end, its interior will be a revelation to the surgeon. Whereas the outside may preserve the cylindrical form of a normal appendix, and may give little or no evidence of inflammation, the interior (if the patient has had one or more attacks) will show one or several of the following conditions. These are illustrated by the annexed cuts, selected from a considerable number of appendices removed by me during the past four months:

1st. A fæcal concretion blocking the canal (Figs. 2, 3, 4).

2d. Interior ulcerations (Figs. 5, 6, 7).

3d. Cicatricial strictures, often of pinhole aperture only (Figs. 8, 9, 10).

4th. Multiple strictures with intermediate pockets, containing suppurating and catarrhal products, and confined by greatly hypertrophied muscular and mucous coats (Fig. 11).

5th. Partial obliterating appendicitis (Fig. 12).

These five varieties are subject to infinite variations. Indeed, I find no two alike.

The condition resembles very much cicatricial strictures of the urethra in some cases. As far as my study goes, I am led to assign three distinct causes which may result in the obstruction which leads to ultimate gangrene, perforation, or rupture following distention:

First, a catarrhal inflammation alone may be followed by stricture, as in the urethra. This form has been distinctly classified by Dr. W. H. Draper as coincident with or a sequel of an attack of grippal influenza. In a paper read by him two years since, before the Practitioners' Society of New York, he ventured the explanation of a lurking remnant of influenza in the appendix, as a reasonable way of explaining the increase of appendicitis in recent years.

Second, a natural point of flexure in the appendix (due usually to an abbreviated point in its mesentery) leads to an arrest of its fæcal contents, which, being inspissated, grow into a concretion. In Fig. 2 this is well shown, and opposite to it a sacculation is commencing, which does not show on the outside, but which was ready to perforate at an early opportunity. This patient had been treated for a year for ovarian inflammation, the symptoms being due to the appendix, as shown by her normal ovary at operation.

Third, an otherwise healthy appendix may be the subject of circular ulceration, from no apparent cause other than probably microbic origin. These after healing are probably the cause of the sharp annular strictures so often seen.

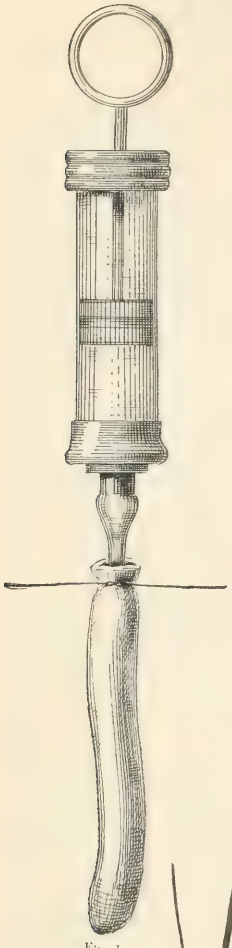
Doubtless many of the cases of spontaneous cure after frequent attacks pass into the stage represented in Fig. 11 (which I find quite common), in which an extreme proliferation of the mucous coat ultimately obliterates the canal—as in Fig. 12. But the patient runs the gantlet of many attacks in which distention of the intermediate pockets may and often does cause fatal results.

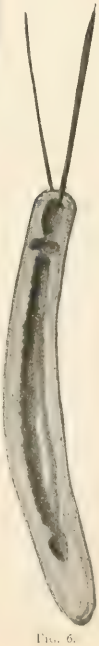
The final obliteration of the canal, moreover, does not always rid the patient of pain. The lady from whom the specimen shown in Fig. 12 was removed had for more than a year been disabled from household duties by appendical pain, yet I found merely this little atrophic organ—which evidently in its cicatrization must have included nerve filaments which disturbed her whole system.

In another case—that of a child aged eleven, whose appendix was almost the counterpart of the one shown in Fig. 11—only one distinct attack of appendicitis had ever been known, and that occurred two weeks prior to operation; but it was evident that perhaps years had been required to produce the chronic changes shown—and this disturbing organ, unrecognized, might well have been the cause of the very puny, ill-developed condition of the child, who scarcely seemed larger than a girl of seven years.

The examination of the concretions is of much interest. Microscopic study of the unstained and stained bits taken from the centres of many of them shows that they are uniformly composed of the inspissated remnants of the contents of inflamed appendices. The pus cells make up the greater part; exfoliated epithelium cells nearly all of the remaining bulk; and, added to these, a smaller part composed of minute bits of meat fibre (nearly digested) and starch cells, with occasional crystals of decomposition—all welded together by a great variety of bacterial *débris*. In the presence of the latter we see the evidence of nature's effort to remove the incarcerated residuum of decomposition and inflammation, and it is possible that it might be accomplished in months or years of waiting.

But who can afford to wait the perilous delay, when the surgery of the day offers safe and speedy relief? It is now possible by recently perfected methods to remove these dangerous chronically inflamed organs through a small incision (usually one inch long), and





leave the abdominal wall practically normal both in appearance and function.

The foregoing demonstration of the interior pathological appearance of the appendices, which, when seen at operation, often present little or no gross appearance of previous inflammation makes it the imperative duty of the surgeon at operation to remove such an organ, whenever the clinical history of a previous attack has been clear, and to subject it to this method of preparation after removal.

In Fig. 4 we have an excellent illustration of several phases of appendicitis. The specimen was removed from a boy of fourteen years, who had suffered four grave attacks during two years. The operation was done during an interval. A concretion of the usual type was found incarcerated in a sacculus at the end of the organ. The alcohol distending the specimen passed through a pinhole opening in a tough stricture, and it was thus hardened in just the condition representing the inflammatory distention of an acute attack, there having been also a stricture at the point where the appendix was cut off.

One may read the past and future history of the trouble in the pathological picture here presented. Perhaps at the next acute congestion of this organ the stricture would become closed; the sealed cavity at the end would then become an abscess, which in rupturing would discharge the concretion.

Regarding these so-called "concretions," it is not well enough understood that, though of variable degrees of hardness, they are not limestones. Concerning their presence, one may repeat the remark of the scientist lecturing on the earth's development, who said: "There are many to whom it is still a mystery how the apple came to get inside the dumpling." The presence of a tight stricture prevents the epithelial scales which are constantly being shed by the lining membrane from being discharged into the colon. This accumulation is by no means a slight matter, and as the laminated deposit increases and dries out it becomes a source of irritation, which adds pus cells to the deposit. Thus the absence of food products from the microscopic examination may be a very striking feature of the stone's composition.

The development of the diseased appendix, therefore, may be said to pass usually through these stages:

First, a catarrhal inflammation of the lining mucous membrane.

Second, irregular narrowing of the calibre, with hypertrophy of the mucous and muscular coats.

Third, strictures.

Fourth, imprisoned food, desquamated epithelium, and pus, forming concretions.

Fifth, obstruction at the stricture, distention, perforation, abscess.

This explanation will, I believe, be found to include the great majority of cases, but does not exclude appreciation of the rarer ones resulting from simple flexion of the organ, or those resulting from internal ulceration.

The Latest Application of the Roentgen Ray is in the tracing by Kümmel of the course of a Murphy button through the intestine.

TWO CASES OF ERYTHROMELALGIA (MITCHELL).[1]

By D. W. PRENTISS, M.D.,

WASHINGTON, D. C.

Case I.—Erythromelalgia (red neuralgia, Mitchell). Mrs. C——, aged fifty-eight years, neurotic diathesis, but has kept up and worked hard in household duties keeping a summer hotel. Before this attack she was "run down" physically. The disease first began in August, 1895, with burning pain in the first finger of the left hand at the angle of the nail next the thumb, and continued for two weeks in the first finger. In the autumn of 1896 it extended to the second and third fingers, then to the fourth, and finally to the thumb.

A large tender swelling developed at the base of the thumb and this winter there is another tender spot on the back of the hand over the third and fourth metacarpal bones, sometimes over the abductor minimi digiti muscle. The pain is of a severe burning character, lasting sometimes for days together, with remission, but it is never entirely absent during the attack.

Fig. 1.—Shaded areas show location of pain.

Fig. 2.—Shaded areas show location of pain.

The ulnar artery was cut at the wrist several years ago by a broken lamp chimney, and was tied. The patient thought perhaps the nerve was injured and this caused the trouble. This is hardly likely, however, as the pain began and has been most severe on the radial side. Stimulating the ulnar nerve at the elbow causes twitching of the third and fourth fingers.

The character of the pain during an exacerbation is of a severe burning nature and paroxysmal, but the parts are always tender until the attacks pass off; then there will be freedom from pain until the next attack. Previous treatment consisted of local applications, such as chloroform, tincture of iodine, blistering, etc., and general treatment in the form of tonics, and especially for dyspepsia.

Paroxysms of pain were in recurring attacks from three to six weeks apart. Pain was less on lying down. Had typhoid fever thirty years ago. No history of malaria or of specific disease.

October 31, 1896, she came under my care suffering from the symptoms just stated. The pain was evidently very severe, as shown by the facies. It was felt most severely in the thumb and first and second fingers of the left hand, which were of a purplish red hue and swollen.

The worst pain was in the ball of the left thumb,

[1] Read before the Association of American Physicians, May 4, 1897.

which was swollen and very tender. The general health was impaired: heart's action weak, but otherwise normal. She was very nervous and slept badly on account of the pain. There was also pain up the arm to the back of the neck, described as a drawing pain, extending also to the ears, jaws, and throat, with a dull ache of the head and blurring before the eyes.

No dizziness, but occasional difficulty in walking (ataxia). Knee jerk normal.

Dyspeptic symptoms very marked, and aside from the pain in the hand the ailment which called especially for treatment.

The character of the indigestion was that common in neurasthenia, from innervation, not from organic stomach disease. For relief of pain:

R Phenacetin . . . . . ʒ ij
Caffeinæ . . . . . gr. j
In ten caps. S. Two every hour until relieved or until six are taken.

Usually one dose gave partial relief.

She was given nitroglycerin, one and one-half milligrams, three times a day, with tonics and bismuth and carefully regulated diet. After two weeks of this treatment without benefit, galvanism was applied from the hand to the back of the neck daily, three minutes at a time at first, the length of application being gradually increased until fifteen minutes was reached. This was continued with the nitroglycerin and tonics for a month without apparent relief, the dull pain still continuing. It was then stopped for a while, but the pain became worse, and galvanism was again resorted to. The relief, however, was nothing to boast of, though it appeared to be the treatment that offered the best hope of good result.

Fig. 3.—Erythromelalgia. Mrs. C., showing character of the swelling. From a photograph.

The nitroglycerin was to strengthen the action of the weak heart and stimulate freer passage of the blood through the capillary system by dilating arterioles. The constant current, with the positive pole in the hand and the negative at the back of the neck, should relieve pain in the hand and relax spasm.

The treatment here outlined was carried out for three months with little or no relief. The patient improved somewhat in general health, however, but there was no improvement of the pain in the hand. It fluctuated, sometimes better, sometimes worse, until February 18th, when the most violent attack of all occurred, the pain being of an intense burning character, extending to the whole hand, though more severe at the points previously indicated, and following up the arm to the shoulder. The color was purplish-red, with œdematous swelling of parts most affected. The last joint of the middle finger was livid, as from strangulation, and appeared as though gangrene might follow.

During the previous night she had taken six capsules of phenacetin and caffeine (of the former 1.20 grams in all) without relief of pain, but with profuse sweating. Holding up the hands gave relief.

A prescription containing extract of cannabis indica, 0.03; extract of belladonna, 0.01; and salicylate of cinchonidine, 0.20, to the dose, to be taken every three hours, was ordered. And at night a hypodermic injection of morphine and atropine was given, which secured relief and a good night's rest. The pain returned with less severity the following day.

The hypodermic was repeated the next night in smaller dose with the same good effects, and then was no longer needed.

Case II.—Mrs. A——, widow, aged thirty-seven years, a neurasthenic, with severe dyspeptic symptoms. No constitutional taint, as far as known. No history of malaria. Pain in heels began three or four years ago, and has recurred at intervals of three or four months, the attacks lasting from two to three weeks. During the intervals she is comparatively free from pain, but is never free from dull aching which constantly reminds her of something wrong about the feet, and her shoes often feel too tight.

The paroxysms seem to be brought on by physical exhaustion or any kind of strain on the nervous system, especially if she is obliged to stand or walk more than usual, as on one occasion when called to nurse her mother in a prolonged illness.

The pain begins as a dull ache with a burning sensation, at first with a feeling as of pebbles under the heels. As the attack progresses, the burning increases, and extends to the soles of the feet and up the calves of the legs. When the pain becomes severe, the heels are red and swollen, and shoes cannot be worn. As the attack increases in severity, a peculiar sensation extends to the head, with restlessness and hysterical symptoms and a disposition to scream. When asked as to severity of pain, she said it was so bad that she felt that she "just could not stand it another moment."

Lying down relieved, except when at the worst; then the restlessness forced her out of bed, and rubbing would give temporary relief. Cold relieved. Putting the feet out from under the cover was grateful. At my suggestion cold water was tried with benefit. Attacks were more frequent and worse in summer than in winter, and also when the feet got warm in bed.

She is drowsy and dizzy much of the time and frequently shows an ataxic gait.

Treatment has been directed to the general condition—the dyspeptic and neurasthenic symptoms. She has an idiosyncrasy against strychnine, the latter causing dizziness and vertigo. No disease of special organs discoverable.

This disease is undoubtedly a rare one, and fortunately so, for, as Dr. Mitchell says, treatment is almost unavailing, though patients often go on for years without becoming worse. It occurs almost always in the feet. Out of sixteen cases reported by Dr. Weir Mitchell[1] in only one was it in the hands alone, and in two the feet and hands were both affected. In all of the others it was in the feet. He gives as the characteristic symptoms redness, intense burning pain, and at the beginning rise of temperature, but later fall of temperature, with probably inflammation of the nerves affected. It usually commences in the ball of the foot, or the heel, or the great toe, and extends to the sole and dorsum. The disease is more common in men than in women. Twelve out of sixteen cases, reported by Dr. Mitchell, were in men, and of twenty-seven cases referred to by Lannois only two were in women.

Another peculiarity of this affection is that it is aggravated by heat and relieved by cold. In Dr. Mitch-

[1] American Journal of the Medical Sciences, vol. lxxvi., 1878.

ell's cases relief came from lying down, although in a case treated by prolonged rest, while the patient was perfectly comfortable in bed, the pain returned in full force when she got up and walked.

In the first case here reported, cold does not relieve the pain and but little relief accompanies the recumbent posture; probably because it is in the hands instead of in the feet. The causes of the disease are obscure. It seems to follow a depressed state of the nervous system, neglected neurasthenia, long standing on the feet, long marches, as of soldiers, reflex irritation, especially of the male urethra. But the disease is so rare and these reputed causes so common that such reference is unsatisfactory.

As to diagnosis in erythromelalgia, according to Dr. Mitchell, there is in a well marked case no other disease or group of symptoms with which it can be confounded. There are many painful affections of the feet and hands, such as the effects of gout, rheumatism, sprain from flatfoot, nodes from syphilis, etc., but none in which exists the train of symptoms found here; and that the disease is rare is evident from the small number of reported cases

As to pathology, it is obscure. Some of Dr. Mitchell's cases ended in cerebro-spinal disease.

The "red neuralgia" expresses only a symptom.

The pathology of these cases is involved in doubt. Erythromelalgia is classed among the vasomotor diseases.

The pain either precedes or is simultaneous with the redness and swelling. In the case of Mrs. C—— they came on at the same time.

In the second case pain preceded the redness. This would seem to indicate that the sensory fibres of the nerves were first affected, the vasomotor becoming involved secondarily as a result.

This also was borne out by the severe pain on pressure at points most affected. With the redness and swelling, however, the pain is greatly aggravated.

The diseases to which it is most nearly allied are angio-neurotic œdema and Raynaud's disease.

In the former there are three forms described—the pale form (neuro-lymphangioma), due to dilatation of the lymphatics and of paretic origin; the red form, due to angio-paralysis; and the dark-red purplish form, caused, according to Eskridge,[1] by spasm of the arterioles, which "checks the *vis a tergo* of the arterial current in propelling the current forward, and spasm of the small veins, which may force the blood backward into the arterioles."

Some such explanation as this may apply to erythromelalgia, but is altogether hypothetical.

Angio-neurotic œdema is supposed to be a form of urticaria, "the greater urticaria"—a functional nervous disease caused by indigestion or transient nervous excitement. In some of the cases which I have seen it has been attributed to spider bite, I need not say without cause. The element of pain is secondary in angio-neurotic œdema and not important.

This disease cannot be confounded with the one under consideration. The diagnosis from Raynaud's disease, though still more marked, deserves special notice, since many of the cases of erythromelalgia reported by Mitchell were pronounced by high authority to be cases of Raynaud's disease.[2] The two diseases in many respects are the opposite of each other. This is perhaps best shown in the comparison in parallel columns given by Lannois.[3]

This comparative statement should make it clear that erythromelalgia and Raynaud's disease are distinctly separated.

Erythromelalgia.	*Raynaud's Disease.*
Sex, four-fifths females.	In twenty-seven cases two were females.
Begins with ischæmia.	Little or no difference in color, until foot hangs down in upright posture, when it becomes rose red.
Affected part becomes bloodless and white. In certain cases there is the deep, dusky congestion of a cyanosed part, with or without gangrene.	Arteries throb and parts become of a dusky red or violaceous in tint.
Pain may be absent or acute, and comes and goes; has no relation to position. May precede local asphyxia.	Pain usually present; worse when part hangs down or is pressed upon. In bad cases more or less at all times.
Unaffected by seasons. In many cases all the symptoms can be brought on by cold.	Worse in summer and from heat. Eased by cold.
Anæsthesia to touch.	Sensation of all kind preserved.
Analgesia.	Hyperalgesia.
Temperature much lowered and unaltered by posture.	Temperature greatly above normal. Dependency causes in some cases increase of heat, in others lowering of temperature.
Gangrene local and limited; likely to be symmetrical.	No gangrene; asymmetrical.

Two other conditions are mentioned as belonging to diseases of the vasomotor system, namely adiposis dolorosa (Dercum's disease) and acromegaly, both attended by peculiar changes of nutrition and without doubt arising from disease of the central nervous system.

In acromegaly "there were found enlarged pituitary body with enlarged sella turcica, persistence of the thymus gland, and hypertrophy of the fibres and glands of the vasomotor system."[1]

These facts are mentioned as having a bearing upon the plausibility of erythromelalgia being essentially a central disease.

There is the more reason for this hypothesis in the fact that a number of the cases reported developed into well-marked disease of the cerebro-spinal axis and ran their course to a fatal result (Mitchell). Dr. Mitchell was disposed at first to this opinion, but in his recent work[2] he "inclines rather to some form of that new clinical perplexity, peripheral neuritis."

The action of ergot (ergotism) in producing gangrene of the extremities is of interest as bearing upon the general question of causation of vasomotor affections by central disease. Ergot acts upon the vasomotor centres in small doses by stimulating; in large doses by depressing.[3] Dr. H. C. Wood mentions a case[4] of fatal ergot poisoning in which there were gastric irritation, thirst, diarrhœa, burning pain in the feet, and convulsions.

The principal vasomotor centre is in the medulla oblongata, between the corpora quadrigemina and calamus scriptorius.[5] Also in the spinal cord, are secondary centres in the gray matter as far down as the lumbar vertebræ.[6]

Dr. Schenk, in an article published recently in the *Medicinische Presse*, states that the disease is no doubt due to vasomotor disturbance consequent on an ascending degeneration in the posterior column of the cord. Woodnut has also described a case of erythromelalgia due to myelitis.[7]

Referring again to Mitchell's "Clinical Lessons," he says: "At the time I wrote (1878) I should, if driven to be positive in statement, have inclined toward considering this malady as due to some form of spinal disorder. But at present the reasonable explanations

incline rather toward some form of that new clinical perplexity, peripheral neuritis."[1]

In Case LVIII. (of "Clinical Lessons," not the fifty-eighth case of erythromelalgia) the disease was the result of an injury, a stone falling on the foot. This case is reported in great detail and serves to strengthen the theory of peripheral neuritis, from the fact that it was caused by (or followed) a local injury. Dr. Mitchell further goes on to say: "I use the word neuritis, nerve-end neuritis, with more or less doubt. Some such distinct affection of the smaller nerves does seem to me probable, but whether it is congestion, neuritis, or some other of the undescribed changes in the lesser nerves or in the ultimate nerve plates, we may not as yet describe with certainty."

Again[2] "neuritis is becoming a sad puzzle. We may have it with paresis and little pain; we may have it without notable paresis and horrible pain. It exists with or without notable myositis.

"Again, it may give rise to causalgia, joint troubles, and alterations of nails and hair. It may fail to disturb nutrition or greatly to alter local heat. And lastly, if erythromelalgia be a neuritis, it may cause pain and flushing, and to these, increased enormously by dependency of the part, may add such a rise of temperature as is rarely seen in acute local inflammation."

Dr. Mitchell continues to discuss the possibility of the existence of neuritis of such a character as to single out individual elements in a nerve containing fibres of sensation, motion, nutrition, and vasal control, affecting some and not others. Such a hypothesis seems untenable.

In Case LVIII., previously referred to, the excised portions of the musculo-cutaneous and internal saphenous nerves were examined microscopically and found "absolutely normal."

To sum up the pathology, then, we have the choice between:

1. Disease of the central nervous system.

2. Peripheral neuritis affecting principally or only the smaller nerves or nerve endings.

If the former, we should expect the disease to be located in the medulla oblongata between the corpora quadrigemina and calamus scriptorius, or in the posterior segment of the spinal cord as far down as the lumbar vertebræ.

The central theory seems the more plausible, but at this time is purely hypothetical, there being no dissections to support it.

The opinion of peripheral neuritis of a peculiar character is given a show of plausibility from two cases, reported by Dr. Mitchell, which followed local injury. In both of these nerves were exsected, and the nerve trunks thus removed found normal. This fact would locate the neuritis in the nerve extremities.

We will close this report by a reference to treatment, which unfortunately can be shortly disposed of. Thus far curative treatment has been of no avail, except in one case, by surgical interference.

The treatment divides itself into three indications:

1. That of the general health, neurasthenia, nervous dyspepsia, and hysteria especially.

2. The relief of pain. For this purpose phenacetin protected by caffeine seems of first value. Cannabis indica and belladonna in the first of the present cases proved useless, as did also the phenacetin in the most violent paroxysms.

During the latter, subcutaneous injection of morphine is imperative, but the objection to its frequent use is obvious. Rest in bed and cold applications are palliative. Wendel reports a case cured by liquor acidi arseniosi, together with general treatment.[3]

3. Surgical treatment. Exsection or stretching of the nerves was contemplated in the first case, but there being no precedent for it, and fearing serious nutritive changes, it was not determined on. This was before seeing Dr. Mitchell's "Clinical Lessons," 1897, in which he reports two cases thus treated, the first one with success in relieving and curing the patient. In the second case, however, gangrene, resulting fatally, followed. The operation, the first of its kind in this disease, I quote from Dr. Mitchell's book:[1]

"Dr. Keen operated on April 10th. He exsected two and one-half inches of the musculo-cutaneous nerve, and the same length of two branches of the internal saphenous. The two end branches (plantar) of the posterior tibial nerve were stretched at the internal malleolus with a traction of fifteen pounds thrice used. The result next day was remarkable. There was almost immediate relief. The foot could be squeezed, pinched, or pricked without pain. Anæsthesia was not so extensive as we were led to expect it might be. Temperature the day following the operation: right, 95° F.; left, 93.5° F.; mouth, 99.5° F. (It was the right foot that was operated upon.) On

Fig. 4.—Shaded areas show location of pain.

the right clonus was still present and knee-jerk was still extensive. The wound healed in a few days. The 4th of May the patient was able to walk on crutches. Clonus had disappeared and reflexes were no longer exaggerated. There was still some flushing when the foot was pendent, but no pain or hyperæsthesia. When discharged May 6th, he could walk well, but was ordered to continue the use of crutches as a measure of precaution and had also a bandage applied daily.

"Dr. Kyle reports culture of blood and nerves obtained at the operation as yielding purely negative results. . . . June 7th, S—— is reported well and walking easily without crutches. Six months later he was at his work as a stone mason and entirely free from pain."

Thus it appears that at least one was cured by surgical procedure. The second case thus treated[2] was more unfortunate. I will only mention the operation and result.

Operation, April 12, 1894, by Dr. T. G. Morton. Four inches of the musculo-cutaneous nerve and five inches of the internal saphenous excised. The posterior tibial behind the internal malleolus stretched with force of twenty-eight pounds. On the fifth day gangrene developed. A week later amputation was performed, with death on the operating-table. Com-

[2] Case LIX. of "Clinical Lessons."

menting on this case, Dr. Mitchell says: "As to operative relief I think that in the future I should stretch all the nerves and leave resection of their trunks to be resorted to if milder means gave no fortunate results."[1]

In conclusion I append titles of bibliography of erythromelalgia taken from the card catalogue of the library of the surgeon-general's office. These titles do not appear in the large published "Index Catalogue." The disease had not been differentiated at the time the volume of the "Index Catalogue" in which they would have appeared was compiled.

A STUDY OF DIET AND NUTRITION IN RELATION TO CONTAGIOUS DISEASES AND TO THOSE DUE TO DISTURBED DIGESTION AND ASSIMILATION.

By E. PALIER, M.D.,

NEW YORK.

THE question of diet dates back for centuries. Since man acquired the power of thought and analysis, dietetics have entered a great deal into his consideration. In spite of this, we are no nearer now to a solution of this vital question than we were centuries ago, the views held with regard to it being in certain regards diametrically opposed to each other, each side strenuously advocating a certain regimen in health and in disease, with apparent equal show of logic and reason.

It is quite interesting briefly to review the opinions expressed by the great masters of the human mind and thought with regard to the kind of diet most suitable for man. The Bible lays down strict rules with regard to dietetics. Though it does not forbid animal food, yet it eliminates the greatest part, and allows only certain ruminants and some birds. The prohibition of cooking the offspring in its mother's milk is probably more on account of cruelty than for hygienic reasons.

Among the lay writers we find that as far back as 570 B.C. Pythagoras was against flesh eating. Plato followed in his footsteps and was a vegetarian, or at least tried to be as strictly vegetarian as circumstances would allow. Hippocrates, in his writings on regimen, favored a vegetable diet as the one conducive to good health, and so did Esculapius. The same views were held by Ovid about 50 B.C. Diogenes and Plutarch held that only ferocious animals ate flesh. The early Christians taught a moderate diet, and deprecated the practice of flesh eating. Cheyne, a celebrated English physician in 1671, maintained that it was possible to avoid and to cure diseases by adhering to a vegetable diet. Pope inclined toward a vegetable diet. Linné said that this species of food was the most suitable for man. Dr. Lambe, in 1765, held the same views. Buffon, Lamartine, Schopenhaur, and Rousseau were against flesh eating. Liebig states the following: "A bear was peaceful and tame as long as it was fed on bread, and a hog after partaking of flesh became ferocious and ready to attack a human being." A German philosopher once said: "Der Mensch ist was er isst." And this probably applies to other animals as well as to man.

When we come to regimen in pathological conditions opinions differ widely. In typhoid fever the diet is a stumbling-block to therapeutists. Bauer recommends beef tea in this disease; some again advise milk. Dujardin-Beaumetz advises preparations of fruits and farinacea. He also recommends a vegetable diet in certain forms of dyspepsia, whereas most physicians find that starchy food, in general, is not well borne by dyspeptics.

In view of the above-mentioned array of great names against an animal diet in health, and the conflicting views of modern therapeutists with regard to the dietary in disease, the question arises: "Have we the right to slaughter animals and be guilty of a wilful and wanton act of cruelty, when it is not only without benefit, but even injurious to our health and morality?"

If we can demonstrate that an animal diet is necessary for man, then we are fully justified in doing so from the principles of self-preservation. But, unfortunately, modern science can help us very little in this regard. Chemically the animal and vegetable proteids do not differ. Physiologically they also seem to act alike. Foster has the following: "Vegetable proteids appear to undergo in the alimentary canal the same changes as do animal proteids, and the effect seems to be the same on the body."

We must therefore consider the question from an etiological standpoint, and see what influence diet has in preventing and causing diseases; and this is a most difficult problem, since such complex phenomena are capable of different interpretations.

At first it is necessary briefly to consider the food stuffs and their ultimate functions in the economy as far as they can be ascertained in the present state of physiology.

The food stuffs are as follows: Proteids, carbohydrates, fats, and fruits.

All agree that all of the above-named food stuffs must enter in various proportions into the dietary of man to maintain health and life. The question is only as to whether vegetable proteids alone are sufficient, or there must be also animal proteids.

The physiology of digestion, the changes which the various food stuffs undergo in the various parts of the alimentary canal are, with the exception of some minor points, pretty well established.

When we come, however, to absorption of the various food stuffs and their ultimate functions in the economy, we are groping in the dark. According to Foster, the fats are absorbed mainly by the lacteals and pass through the thoracic duct into the venous system. The sugars are absorbed mostly by the capillaries of the villi, through the intestinal epithelium, and thus enter into the portal vein. The absorption of the proteids or peptones is less understood and more difficult to follow. Foster inclines to the view that they are absorbed mostly by the capillaries, but as soon as they pass into the blood all trace of them is lost. The difficulty attending this subject is apparent.

Some claim that the leucocytes are mostly concerned in the absorption of fats and proteids. Though this view is discredited by physiologists, yet it is admitted that the leucocytes do ingest in themselves particles of food stuffs and other foreign bodies reaching the system. With regard to the ultimate uses made by the body of the various food stuffs, the trend of opinion is that the proteids are mainly concerned in tissue metabolism, and are excreted by the kidneys as urea in carnivorous animals and mostly as uric acid in birds and reptiles.

The proteids, however, when partaken of above a certain mark, may by themselves constitute the luxus consumption, and an animal may gain flesh. The fats and carbohydrates are mainly concerned in supplying the body's energy in its various forms. They are also stored up as adipose tissue, as a reserve to be drawn on whenever necessary.

This is a brief summary of the food stuffs and their destinations, which it will be necessary to bear in mind in the further discussion.

It would seem, then, that a man may live on a vegetable diet and yet continue to be in apparent good health and capable of performing prodigious amounts of labor, as is proven by the European, especially the Russian, peasantry, as well as by the Asiatic laborers, namely, Japanese and Chinese, who, though feeding almost exclusively on vegetables, yet are capable of performing continuous fatiguing labor; and this is the case with the equine race. The opinion generally held that the Esquimau and other Northern races are stunted in growth and physically weak on account of their animal diet is lacking of proof, for there are many other factors obtaining there, so that it is hard to say what part diet plays under those circumstances.

When, however, we come to the clinical history as well as the morbid changes in a vast number of diseases, there seems to be very little difficulty in tracing them to errors in diet, and the animal diet seems to exert a powerful influence on the economy by enabling it to resist a great number of diseases. There are, however, affections which can be traced to errors of either the one or the other kind of diet, as I will try to demonstrate.

Gout is a disease *par excellence* which is due to an excess of concentrated vegetable principles partaken of by man. In the ancient times gout was prevalent mainly in the upper classes. Since the introduction of malted liquors, gout is quite prevalent among the poorer classes. The morbid changes in gout are an increase of urates, especially that of sodium, in the blood and tissues. Now, uric acid in the form of urates is the characteristic in the urine of birds, which feed mostly on grain, vegetable proteids. Foster denies that uric acid is due to deficient oxidation, and believes that it is an independent product, as urea. And this cause of gout is in accord with the clinical experience in treatment. Sydenham and others thought that farinaceous food was suitable in gouty conditions, laboring under the impression that it is due to an excess of animal food. But the fact is, it is due to an excess of vegetable principles, and this is in accord with Dr. William H. Draper's experience,[1] who says that albuminous food is most acceptable to gouty patients, and farinacea should be excluded as much as in diabetes.

Rheumatism is a disease which is generally considered as being more or less allied to gout, and is classified with the latter. There is sufficient evidence that it is a disease due to disturbance of nutrition, such a theory having been advanced already by some. The microbic theory of rheumatism advanced by Heuters and others does not preclude the fact that the main predisposing cause of this disease is a disproportionate supply and demand of the various food stuffs. Prout's lactic-acid theory was modified by the sarcolactic-acid one; but both acids belong chemically to the same group, and both are derivatives of the carbohydrates. The carbohydrates, according to Foster, are mostly made use of by the muscles for kinetic energy, and are given off as CO_2 by them. The uric metabolism is but slightly increased during active muscular exercise.[2]

Now when the supply of the carbohydrates is greater than the demand, there results a disturbance of nutrition which manifests itself as a symptom in the acids of the perspiration; the economy is thus susceptible to a disease which is brought about by exciting causes. Loomis says: "Scrofula, phthisis, and cancerous affections so often precede rheumatism that a connection between them cannot be denied."

Phthisis I will discuss later, and propose to prove that the effect of diet on it is admitted by most.

A remarkable fact about rheumatism is that suckling infants are almost exempt from it. Rauchfuss found only two cases of it among fifteen thousand suckling infants, and such is the experience of other observers. If we take into consideration that the sugar of the milk is proportionate to the demands of the infant, milk being its natural food, the exemption of infants from rheumatism is explicable.

Dr. Percival, in 1754, wrote about the benefits derived from cod-liver oil by fishermen suffering from rheumatism. Dr. W. H. Thomson recommends it highly in this affection, though from another standpoint, for according to him it is a skin disease. But the fact remains that cod-liver oil is beneficial in many cases of rheumatism, and this helps to confirm the view that it is a disease due to disturbance of nutrition, and the disturbance is caused by the disproportionate supply of the food stuffs.

Hence both rheumatism and gout are diseases caused mainly by an excess of carbohydrates, but whereas in the latter the mischief is due mainly to the nitrogenous

[1] Pepper's "System of Medicine," vol. ii., "Gout."

[2] Foster, § 539.

elements, in the former it is due to the non-nitrogenous elements.[1]

Diabetes mellitus is a disease that has been known for centuries, and has been widely investigated of late; yet its etiology and pathology have not been satisfactorily explained so far. Aside from the nervous origin of diabetes, which was established by older observers, recent observers have laid great stress on pancreatic diabetes.

Dr. Kaufman, in an exhaustive article on this subject,[2] tries to explain the relation of the pancreas to the sugar formation of the blood. He inclines to the theory that the pancreas has, *per se*, aside from its secretion, an intrinsic control over the sugar ferments of the blood, and that when this intrinsic power is gone there is an excess of sugar formation. He cannot explain, however, what this power is, and how it acts. Pathologically we find a hyperæmia of the liver in diabetes, and sometimes it is in a hypertrophic and cirrhotic state. Writers try to explain the hyperæmia as being due to affection of the vasomotor nerves controlling the liver. Yet competent observers have failed to demonstrate any nerve lesions in many cases of diabetes.[3] The fact is that though hyperæmia will follow vasomotor paralysis, it does not necessarily follow that the cause should originate in the nerves, as many local irritants will cause hyperæmia as well. It is highly plausible to assume that diabetes is in most cases a dietetic disease, and it is akin to dyspepsia.

Now, what is dyspepsia? It is an affection characterized by digestive disturbances of one or several parts of the alimentary canal. It is hardly necessary to say that unsuitable diet and irregularity of meals are the most prolific causes of dyspepsia. It may also be caused, as a rule temporarily, disappearing as soon as the cause is removed, by worry, anxiety, fright, etc.; in fact, by nervous affections. Digestive disturbances may be gastric, or pancreatic and hepatic, or all forms combined. Gastric disturbances not being an essential part of the subject under discussion, I will not dwell upon it.

Dyspeptics are variously affected by the several articles of diet. A great many cannot easily digest fats and carbohydrates. In such, a fatty meal causes pyrosis, malaise, and semisolid fatty mucous stools; carbohydrates cause excessive fermentation with borborygmi. Dyspeptics also generally suffer from a torpid liver, with its concomitant, piles. Physiologically it is pretty well established that fats are prepared for absorption by the pancreatic secretion, and secondarily by the hepatic. The carbohydrates undergo amylolytic changes through the saliva, and to a greater extent through the pancreatic juice, whereby they are transformed mostly into maltose, which is absorbed by the liver and is stored up as glycogen, having undergone a retrogressive change. Now, since owing to dietetic errors the fat-transforming power of the pancreas and the liver is often impaired, there is no reason why the same should not happen with the carbohydrates. It is a general law that when the function of an organ is impaired it should not be overtaxed. But dyspeptics, as a rule, and also diabetics, seek advice very late; and meanwhile the liver and the pancreas, having undergone excessive strain while in a weak condition, become hyperæmic—which, by the way, occurs after each meal, especially a mixed diet, even in normal conditions—and this hyperæmia leads to hypertrophy, which may result in cell proliferation and cirrhosis.

Clinically it is a fact that diabetic patients improve on a proteid diet. Some glycosuria will still appear, for proteids are also split up into sugar. Physiologically the pancreas, as I have said, helps the saliva to transform the carbohydrates into maltose, and this is absorbed by the liver and stored up as glycogen. When, however, the amylolytic power of the pancreas is weakened, at the same time the absorbing power of the liver is taxed to the utmost, for it has to absorb material not well prepared; the pathological changes of diabetes will follow, the liver becoming altogether *hors de combat*, and all the glucose formed by the saliva, and which is probably formed by fermentation even in normal conditions to a slight extent in the other parts of the economy, is discharged through the urine. The amount of carbohydrates consumed by an individual is not a criterion, for what may be very small for one may be excessive and deleterious to another. The digesting and absorbing power, as well as the amount utilized for kinetic energy, of each individual must be taken into consideration.

According to Dickinson, diabetes is more prevalent in the agricultural districts of England. This fact, if true, is significant, for agriculturists live mostly on fats and carbohydrates.

In short, then, diabetes is akin to fatty dyspepsia. The same pathological changes in the pancreas and liver are apt to occur in the latter after a time as in the former.

Tuberculosis is a disease which greatly occupies the attention of the medical profession at present. Since the discovery by Koch of the tubercle bacilli, in the last decade, the trend of opinion of the profession is to regard it of microbic origin and to consider it among the contagious diseases.

Now there are remarkable phenomena with regard to the microbic diseases, which so far either have not been explained at all, or are explained by the vague term idiosyncrasy; namely, that certain ages and localities have a relatively greater immunity than others. As I intend to dwell on each disease separately, I shall consider these points in connection with each.

With regard to tuberculosis, we find that infants under one year and the aged are less subject to it than older children and adults. Dr. A. Jacobi,[1] in summarizing this subject, says: "Thus tuberculosis is comparatively rare under one year, undoubtedly because of the comparatively few opportunities for infection." It is, however, quite incomprehensible why infants have fewer opportunities for infection than children and adults. Infants under one year are comparatively under worse hygienic conditions, for they are kept more confined and enjoy less the benefit of fresh air. In the poor districts of the larger cities, infants are kept for days and occasionally for weeks without getting an airing, confined in unventilated, overcrowded, unclean rooms of tenement houses, which are generally the starting-points of all contagious diseases, as is well known to every observer. The schoolhouse and the factory are certainly under more favorable hygienic conditions than is the tenement house. Infants of tuberculous parents, or in a family in which there is a tuberculous member, are thus constantly inhaling the dried tuberculous sputum under conditions most favorable for the development of tuberculosis. The period of incubation of tuberculosis is admitted not to extend over a year, but is counted by weeks, so that tuberculosis should be at least as prevalent among infants, if not more so, as among children and adults.

When we come to old age, we also notice that tuberculosis, as well as most contagious diseases, are comparatively rarer then than at the other periods of life.[2]

[1] An excess of the carbohydrates and the fermented and malted liquors is probably also the cause of delaying the metabolism and elimination of the animal proteids, which, accumulating in the system, help to bring about the gouty condition.

[1] Keating's "Cyclopædia of Diseases of Children," vol. ii., p. 168.

[2] Pepper's "System of Medicine," vol. iii., "Tuberculosis, Phthisis."

All this is explained by the obscure term of "diathesis." Geographically three are certain places where tuberculosis is very rare; such are the Faroe Islands and Iceland.[1] Dr. S. Kneeland,[2] who travelled in those islands, says about the inhabitants that they are very filthy, seldom taking a bath, so that vermin are seen crawling on their bodies. They live in crowded, ill-smelling, ill-ventilated rooms, huddled up together. This description is in accord with the statements of other travellers.

Now, supposing that climate exerts a favorable influence, it ought to be offset by the unfavorable hygienic surroundings, so that tuberculosis ought to be as prevalent there as in other places, for who would think of sending people for their health to the Adirondacks, and locate them in overcrowded, ill-ventilated quarters? Would not the Adirondacks become as bad as a tenement house? It is also stated that tuberculosis is less frequent in the navy and more prevalent in the army, and at the same time we notice that with regard to scurvy, a dietetic disease *par excellence*, the opposite prevails. Here, then, we have groups of individuals who are little susceptible to tuberculosis. There is one characteristic common to all of them, and that is their diet.

Infants feed exclusively on animal diet, milk. Old people, being unable to masticate bulky carbohydrates, live largely on milk, animal proteids—the latter, on account of being required in small bulk, are most suitable to that age—and fats. The Faroese and the Icelanders, because of the aridity of their land, live mostly on animal diet. The same is the case with sailors, who consume little of the vegetables and live on preserved flesh and fats, and hence the prevalence of scurvy among them. And this is in accord with what we know of the animal kingdom. We find that the dog and the cat are less susceptible to this disease than other animals. With regard to animals kept in confinement, Mr. Smith, director of the Central Park Menagerie, kindly volunteered to me the statement that the carnivorous animals suffer very little from contagious diseases, but, on the other hand, they suffer and die from intestinal troubles, are subjected to cramps, and convulsions, and kidney troubles; and this is precisely what happens with suckling infants.

Diphtheria is a disease of childhood *par excellence*, and yet infants under one year are very seldom the subjects of it, though unquestionably cases are occasionally met with at that age. Oertel says,[3] with regard to diphtheria: "In the first half-year the infant organism seems to be not at all susceptible to the disease." Jacobi[4] explains this on the supposition that the abundant acid secretion of the mouth of infants after three months of life washes away the diphtheritic infection, and does not give it a chance to gain a foothold in the buccal cavity.

But the fact is that, the normal buccal secretion being alkaline,[5] the acid secretion shows an abnormal unhealthy condition of the mucosa of the cavity, and is generally found in connection with the various forms of stomatitis, especially the parasitic variety due to the saccharomyces albicans.

Now it is quite logical, and in accord with what we know about etiology in general, to expect that with an acid secretion, when the mucous membranes are more or less unsound, diphtheria should set in sooner than otherwise. The acid secretion is certainly valueless as an antiseptic, for, if it were such, how would the above-mentioned parasites thrive in it?

[4] Pepper's "System of Medicine," vol. i., "Diphtheria."
[5] Keating's "Cyclopædia of Diseases of Children," vol. ii., p. 959.

Old age is as little susceptible to diphtheria as infancy, and finally we find that the various parasitic affections of the buccal and nasal cavities, such as glanders, diphtheria, and scarlatinal sore throat, are most common among the herbivoræ and very rare among the carnivoræ. We find, furthermore, the statement made[1] that diphtheria is more fatal in the rural than in the urban districts. Now reasonably we should expect the reverse, since even the poorest of the rural inhabitants are under better hygienic conditions, as far as fresh air, spacious quarters, and cleanliness go, than the poorer classes of the tenement districts of cities. We cannot ascribe the fatality to lack of skilled physicians, for we find that the mortality of this disease is less among the Indians than the whites, and is also less among the blacks—and Indians and blacks, as a rule, care very little about securing the best medical skill; yet they seem to be better off.

If we should consider diet as a great factor in this disease, we can explain the above-mentioned puzzling facts. With regard to Indians and blacks, the race influences probably play also important parts, besides diet.

Measles is another disease remarkable for its greater prevalence at certain ages and in certain localities. Thus, statistics show that it is also comparatively rare under one year, very seldom attacks the old, and is more fatal in rural districts.[2]

With regard to small-pox the same statement is made, though we should expect the contrary, *a priori*, since infants are seldom vaccinated in the first half-year of life, so that small-pox should be most prevalent at that age.

The same is said with regard to typhus, typhoid, and malarial fevers. Though cases of each undoubtedly occur in infants, yet they are less subject to these diseases than individuals of other ages.

Thus we find a number of diseases to which groups of individuals, who *a priori* we might suppose should be more susceptible, are really less so, and *vice versa*. No plausible explanation that could stand a moment's criticism has so far been advanced. Since we find, however, that in those groups of individuals the only marked distinguishing feature to their advantage or disadvantage is their diet, diet then must be the great factor responsible for greater or lesser susceptibility to certain diseases in certain groups of individuals of the same races. I say of the same races, because, race with relation to diseases being a subject for study in itself, I do not wish to broach it here.

With regard to tuberculosis and diphtheria, the influence of diet on them is more evident than with regard to the other contagious diseases. The specific pathogenic micro-organisms of these two diseases have been more satisfactorily established than those of the other contagious diseases, and the advantages of the albuminates and fats seem to consist in enabling the system to overcome the pathogenic micro-organisms. Physiologically we know that albuminates, as well as all the proteids in general, whether animal or vegetable—and the former seem the more so—hasten tissue metabolism, and thus cause cell stimulation, *i.e.*, they hasten the disintegration of the old ones and cause their withdrawal from the economy, and these are replaced by new, more vigorous, and healthy ones. In addition to this, the albuminates and digestible fats seem to be the most suitable nourishment for the leucocytes. As I said above, some claim that the leucocytes are responsible for the absorption of the fats and proteids from the alimentary canal. This view is

[1] Keating's "Cyclopædia of Diseases of Children," vol. i., p. 142.
[2] Keating's "Cyclopædia of Diseases of Children," vol. i., "Measles."

discredited by Foster; but even he admits that the leucocytes ingest within themselves great quantities of these food stuffs. The same cannot be said of the carbohydrates; no observer claims that they are absorbed to any extent by the leucocytes. The theory of the phagocytic properties of the leucocytes is gaining more and more ground. They seem not to take any important part in the constant physiological processes, and are placed mainly as the guardians against foreign intrusion. A great excess of them is detrimental to the economy, and hence the disease leukæmia. To use a simile, they can be compared to a standing army of a commonwealth. In case of war the standing army is increased, and the same is the case with the leucocytes, which increase in number in many communicable diseases. When, however, the army is increased disproportionately to the inhabitants and to the means of the commonwealth, the result is total ruin of the latter as well as of the former.

The case is different with the workers and producers of a community. A general increase of them is always beneficial. So with the tissues performing constant physiological function, a general increase of them is beneficial. There is no disease produced by an increase of red blood corpuscles. The slight inconvenience from the so-called "full-bloodedness" can easily be overcome, and cannot be called a disease. The same with general muscular and nervous development. The adipose tissue, however, being kept merely as a reserve, and being called upon only at certain times for supplies, is injurious by its excessive development.

Pathologically we notice that in most contagious diseases the initial lesion is found somewhere in the lymphatic system, and is propagated to the system through the lymphatics. The tubercle of tuberculosis consists, according to Ziegler,[1] principally of emigrated leucocytes. According to Virchow and Woodward, the tubercle always takes its origin in a lymphatic vessel. In diphtheria the membrane, according to most authorities, is formed by the migration of leucocytes, together with the fibrin derived from the transuded plasma.[2] There being pretty often a glandular enlargement in this disease, it shows that the lymphatics carry the contagion to the body. In typhoid fever we find the characteristic lesions in the intestinal follicles or Peyer's patches. In malarial fever the spleen is greatly affected; and in bubonic plague—a disease, by the way, affecting mostly the Asiatics, who generally live on carbohydrates—the glands are also primarily affected.

How do we explain these phenomena? We can easily explain them by the fact that the leucocytes, which are constantly wandering all over the system, as soon as they meet with the pathogenic micro-organisms engage in a deadly struggle with them, and as soon as the first ranks succumb others advance to take their place in the struggle, and the outcome of this struggle is the survival of the fittest. Since the leucocytes are most abundant in the lymphatics, they are apt to carry at first some of the micro-organisms over there sooner than anywhere else, and hence the lymphatics suffer first and most. To use again the above simile, in a country invaded by a foreign army the signs of battle, whichever side wins, are mostly seen and felt in places occupied by numerous bodies of the defending army.

The action of antitoxin in diphtheria is stated by some[3] to be due to cell stimulation, thus enabling the leucocytes successfully to struggle with the bacilli. This view seems more plausible than the one claiming it to be a chemical antidote. Thus antitoxin would be considered as an albuminoid, and act simply as a food for strengthening the leucocytes.

Modern physiology teaches that the peptones are formed by a process of fermentation due to the development of micro-organisms. Experiments have shown[1] that the gastric and pancreatic juices are not germicides, and the result of the experiments is in accord with the teachings of physiology; if the intestinal juices were germicidal, digestion could not go on, for there could be no fermentation due to the development of micro-organisms. It would also seem reasonable to suppose that the leucocytes normally take care of the walls of the stomach and intestine, destroying the micro-organisms which are apt to adhere to them. The peristaltic movement also prevents the food normally from adhering very long to the walls, so that the main process of digestion is always driven away from the periphery toward the centre. This explanation seems more plausible than those hitherto advanced as to why the walls of the stomach and intestine do not digest themselves. The explanation that the alkalinity of the blood neutralizes the acidity of the gastric juice does not hold good for the pancreatic digestion, which is alkaline. How is this neutralized?

We find the following statement made:[2] "It must not be forgotten that albuminoses are produced by microbes, and these soluble products are capable when injected into an animal of producing immunity against certain diseases." I must add that the same authority considers the peptones as a tox-albuminose.[3]

It is further stated that "Hankin has shown that an albuminose is capable of protecting animals against splenic fever."[4] This brings me also to speak of the action of quinine in malarial fever.

The therapeutic action of quinine in malaria, as well in fact as the therapeutic action of all drugs in all diseases, is rather empirical and obscure. It is claimed by some[5] that quinine acts *per se* as a germicide, destroying the plasmodia in the blood. But, since the plasmodia are endowed with amœboid movement, they most assuredly penetrate into the most intricate recesses of the system, like the leucocytes, and, admitting that the germicidal action of quinine destroys the plasmodia, the whole system must be literally saturated with it in a sufficiently strong solution. Would not this be detrimental to the economy? Besides, if quinine acted as an antiseptic, other antiseptics should also be more or less efficient.

It would seem plausible to suppose that quinine acts like antitoxin by cell stimulation. We find[6] that quinine increases the number of leucocytes. We find also[7] that in malaria the leucocytes are increased in number; quinine thus helps the increase of the leucocytes, to overcome the swarms of plasmodia which invade the system. Quinine has been administered empirically in all zymotic diseases, not simply as an antipyretic, but with the vague idea that it somehow helps along.

Many cases of chronic malaria do not yield to quinine, but are successfully treated by arsenic and strychnine, drugs usually administered as so-called tonics and not as germicides.

In addition to the physiological actions of animal diet, the fact is that it is generally submitted to high temperature before it is used, and is rendered more aseptic than vegetables, which are eaten either raw or cold. It is yet undecided[8] whether or not by eating the

flesh of infected animals the infection will be carried to the system. But to err on the safe side, in almost all civilized communities animals are examined by experts before being used for human food.

The foregoing may be summed up as follows: Animal diet is a good prophylaxis against the microbic diseases. Rheumatism, gout, dyspepsia, and diabetes are less apt to follow an animal diet, these being diseases *par excellence* due to vegetable products. On the other hand, however, animal diet is a prolific cause of acute gastro-intestinal trouble—witness the carnivorous animals and suckling infants, who die mostly from intestinal complaints; it is also a cause of general convulsions and epilepsy. Cases of ptomain poisoning due to an animal diet are reported.[1] The noxious effects of an animal diet, when partaken of injudiciously, are thus evident and palpable, and can in most cases be easily traced to the cause, and that is why it is looked upon by many people with such suspicion.

The carbohydrates, on the other hand, are wolves in sheep's clothing. Unlike the albuminates, they are more apt to undergo excessive fermentation than putrefaction, and thus years may pass, the patient feeling only slight discomfort meanwhile, till its noxious effects break out. It is not surprising then that the primary cause should be entirely lost sight of, and the effects attributed to intermediate secondary causes.

I have traced, as far as it is possible in such an article, the good and the evil derived under certain circumstances from each regimen. It is impossible to lay down general laws as to regimen. Each individual is a subject for separate study, and the best advice that can be given in this matter is: "Man, know thyself."

THE CONDITION OF THE GASTRIC SECRETION IN MERYCISM.

By ANDREW HALLIDAY, M.B.,

SHUBENACADIE, NOVA SCOTIA.

In the Medical Record of June 12th, Dr. Menassian, of Iowa, reports a case of merycism which is very interesting from a professional standpoint, but is doubly interesting to me on account of the fact that I myself have the power of regurgitating and ruminating.

Since my boyhood I have had this power of regurgitating and remasticating my food at will. Indeed, it became so habitual with me that I put the operation into practice after almost every meal, particularly after dinner or when I had taken any specially solid food and which I had not thoroughly masticated, *e.g.*, pieces of meat, hard-boiled egg, etc. It never caused me the slightest discomfort to go through the process, and the food, instead of being in any way disagreeable, was rather rendered more palatable, this being accounted for, no doubt, by the partial conversion of the starchy part of the meal into sugar.

When about eighteen years of age I began to smoke, and since then I have largely given up the regurgitating habit, simply because the one habit has supplanted the other, since whereas I used to regurgitate and ruminate after a meal, I now smoke. Nevertheless, I often, an hour or two after a meal, almost involuntarily regurgitate a mouthful of my gastric contents. These contents, however, are never regurgitated of themselves against my will. I have perfect control of the process, and although I may, indeed, do it involuntarily, still I just do it in the same way as I would, without actually thinking of what I was doing, go and fill and start to smoke my pipe. On these grounds, then, I am led to consider the whole thing merely a matter of habit, and not due to the condition of the gastric secretion. Like Dr. Menassian's patient, "nausea, pyrosis, pain, or distress referable to the stomach" are subjective symptoms which I never experience; neither have I epigastric tenderness nor am I neurasthenic. The only thing I do suffer from is migraine, a subject which I have discussed in this relationship elsewhere.

I have taken Ewald's test breakfast many times, and examination of the gastric contents gives the following results: Reaction, acid; total acidity = 45 to 55; HCl (Günzburg's test) = 0.124 to 0.1604 per cent.; acid salts, small amount; rennin ferment, active in three to five minutes (Leo's method); proteolytic ferment, active for fibrin very quickly.

The gastric contents were usually regurgitated from forty-five to sixty minutes after taking the last mouthful of the breakfast (three hundred cubic centimetres water and thirty-five grams bread). After one hour I was not able to regurgitate enough to go through the various tests, but between forty-five and sixty minutes I could always get more than enough.

Dr. Menassian seems to think that this indicates too rapid a passage through the stomach, but I cannot quite agree to this, and I am supported in my opinion by the following: "As the result of eight examinations on healthy subjects, Boas says that one hour after taking a roll and three hundred cubic centimetres of water, about forty cubic centimetres should be obtained by expression; the amount may vary fifteen cubic centimetres either way; otherwise the result is pathological."[1] According to the above, I have always been within the normal limits.

In conclusion, then, I would call attention to the following facts:

(1) The whole process is absolutely under control of my will (although it may occur spontaneously, as stated above).

(2) HCl is never absent, a point Dr. Minassian lays great emphasis on; and although I have examined very frequently I have never found it, after a test breakfast, below 0.124 per cent. We therefore agree as to a diminution below the normal 0.2 per cent., but not as to the total absence.

Furthermore I have, on getting up in the morning, swallowed one ounce or so of water, and on regurgitating part of it in about two minutes it even then showed distinctly the presence of HCl on applying Günzburg's test.

It seems to me just possible that the regurgitating and remasticating of the food may in the first instance have been an attempt on the part of nature to stimulate reflexly the secretion of gastric juice, considering that it is usually deficient in quality. This, however, is merely a theory, and not, I fear, susceptible to proof.

[1] Ewald: "Diseases of the Stomach," Footnote, p. 19.

Thyroid Extract as a Galactagogue.—Having observed, in conjunction with the good results following the employment of thyroid extract in the treatment of sporadic cretinism, myxœdema, and some cases of mental feebleness, more or less marked increase in the activity of the metabolic processes of the body, Stawell (*Intercolonial Medical Journal of Australasia*, April 20, 1897) was led to believe that the same agent might be reasonably expected to increase the metabolism of the mammary gland in suitable cases. Accordingly he employed thyroid tablets (presumably each representing one grain of dried gland), given from three to five times a day, in nine cases of nursing women, and in seven of these distinct increase in the quantity and apparent improvement in the quality of milk secreted followed.

ON DIGITAL MANIPULATION FOR THE REMOVAL OF A PIECE OF CATHETER OR OTHER INSTRUMENT ACCIDENTALLY BROKEN OFF, AND REMAINING IN THE DEEP URETHRA OF THE MALE.

By JOHN H. BRINTON, M.D.,

PROFESSOR OF THE PRACTICE OF SURGERY AND OF CLINICAL SURGERY IN THE JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA.

THREE times it has happened to me to have an instrument part or break during manipulation in the male urethra. On two of these occasions the instrument was a flexible English catheter of small size, and once it was a filiform, well made from carefully selected whalebone. On the occurrence of such an accident one must act at once; the remedy to be efficient must be prompt. Its necessity is evident not only to the surgeon but to every bystander, and most of all to the patient. I can never forget the wistful expression on the face of the patient of my first mishap, years ago, as I drew from his meatus the anterior fragment of the broken English catheter. "Yes, doctor, I see it has broken off; now what are you going to do about the other piece?"

And this is what I did: Instinctively I placed the fingers of my left hand on the perineum behind the scrotum, and pressing deeply upward and backward, I felt the urethra in front of the bulb. Within its walls I could readily distinguish the broken anterior end of the fragment. Grasping both tightly between my left thumb and index finger, so as to prevent the catheter from slipping toward the bladder, I exerted a dragging force from behind forward in the course of the urethra. By this means the broken end of the catheter started or was drawn forward, apparently half an inch. Then, with the thumb and index of my right hand, I fixed what I had gained, and, moving the left thumb and finger backward, I took a fresh hold and renewed the manœuvre or motion from behind forward, with effect and security. Again and again I repeated this process, each time gaining a little until the ragged upper end of a three-and-a-half inch fragment presented at the meatus.

In a recent instance of a filiform broken four and a half inches from the point the same manipulation was successful. In another case which occurred some years since, the catheter was of such small calibre and had broken so low down that it could scarcely be recognized in the urethra by pressure from without. Here I introduced my right fore-finger into the rectum and then readily detected the point of the catheter in the membranous urethra. I then pressed the end of my forefinger firmly up and against the prostate, so that the catheter fragment might not pass further bladderward. Then, with my left hand resting on the urethra at the scrotal junction, I gently moved my right forefinger in the rectum forward along the membranous urethra. The fragment then moved forward, and so, by a series of alternate motions of the right forefinger, and of relaxation and gripping with the left fingers, the fragment advanced until its progress could be controlled by external manipulations over the anterior penile urethra, whence it was extracted by an ordinary thumb forceps.

I have been lately informed by Mr. C. B. Stevenson, the special nurse of the urinary cases at the Jefferson College Hospital, that in two instances he has, of his own origination, in the same manner successfully removed a filiform which had been lost in the urethra. In both these cases the alternate use of the forefinger in the rectum and of the fingers of the left hand externally over the urethra, as described, brought the errant filiform to the surface.

I may also add that I have satisfactorily employed this method on one or two occasions, in which a patient had broken his catheter in self-catheterization. It is perhaps worthy of note that I have observed clinically that the tendency of a flexible fragment, if left to itself, is to work toward the meatus. This may be due to the direction of the urine flow or possibly to the action of the contractile fibres of the urethra. It is, however, contrary to the generally received opinion that the course of a foreign body, especially if hard and smooth, is inward toward the bladder.

In recapitulation I would state, from my own experience and from cases of which I have knowledge, that in the event of a like recent accident, or in the attempt to remedy one of a previous date, I would first of all insert my finger into the rectum and press against the prostate to prevent the foreign substance from passing deeper. If I could feel it, I would try and work it forward by the alternate movements of the finger of the right and those of the left hand, already described. If the broken portion was lodged in the penile urethra, anterior to the scrotal region, the digital manipulation could be made to act directly upon it, without the insertion of the forefinger into the rectum.

The process I have thus described for the extraction of a retained catheter fragment has, it may be, been used by others. Even if not novel, it is, I think, not generally practised, and I am sure that it may sometimes be resorted to with good effect. It has at least one recommendation; it requires no instruments save those which the surgeon has always with him—his faithful fingers. It has proved of service to me, has spared me some anxiety, and has rendered cutting operations unnecesssary. I therefore submit it, in the hope that it may do as much for some one else.

JUNE 11, 1897.

Clinical Department.

EXSTROPHY OF THE BLADDER IN A GIRL OF THIRTEEN YEARS; OPERATION; RELIEF.

By F. E. TARVER, M. D.,

AUGUSTA, GA.

I MAKE no apology for this paper except the rarity of the case, it being somewhat of an anatomical curiosity.

About twelve years ago a baby was born in Burke County. It soon became rumored that this baby was deformed. I took occasion to call and asked permission to examine the infant. (I had at one time practised for the family.) The request was readily granted. In conversation with the mother I learned that the baby was a girl, and was unlike any she had ever seen. At this time the infant was five or six weeks old, and the mother then had four or five children, all of whom were healthy and perfectly formed.

The infant was exposed for examination, and I found to my astonishment the following condition: The vulva was very large and very much protruded, the labia being widely separated at the top, with a cavity just under the pubic bone, where the urethra should have been. There was a small section of sphincter muscle, but no sign of a urethra; there was an oblong transverse cavity just under the pubic bone, about one and one-fourth inches by one-half inch wide. The labia minora were very prominent and thick; the labia majora were very long and thin, with a V-shaped opening at the top, extending nearly or quite through the mons veneris, and were separated from three-fourths to one inch, just in front of the pubic bone. There was a small strip of bladder tissue lying on top of the vagina and just under the pubic bone, on either side of which the ureters emptied, pouring the water over

the vulva and limbs of the child in an almost continuous flow. The ureters were much elongated. There was no union of the parts from the sphincter of the urethra up through the urethra, bladder, both labia, and upper section of the vulva, and for some little distance in front of and above the pubic bone. The vagina and pubic bone were perfectly formed. The lower part of the vulva was normal. Even at that age there was decided irritation over the parts, which the urine kept continually wet.

The mother asked my opinion, and I advised an operation. She was opposed to that, and called a surgeon from a neighboring town. He thought best to postpone the operation until the child grew stronger.

About six years later I was called to see the child. I found the whole of the inside of the lower limbs excoriated, with ulcers in and around the vulva, and a chronic irritation in and around the oblong cavity before mentioned. Her condition was virtually the same, except that it was greatly exaggerated. The labia majora were much longer, thinner, and very much more separated at the top; the labia minora were immense, very prominent, and lapping together so as almost to cover the oblong cavity. The V-shaped notch in front of the pubic bone was much wider and filled with mucous membrane.

The child was in an awful condition. She never wore dry clothes; she slept in a wet bed; and, as a consequence, was debarred from nearly all the social advantages natural to a child of her age.

I again advised an operation, but my consultant still thought best to postpone. At the age of eight years matters were complicated by the appearance of her menses, which were regular and full, but she did not show the development which usually accompanies this period in a girl's life. I tried every form of urinal, with not only no benefit but often with positive injury. I had several made from original designs, but with no better success.

About this time the consulting surgeon died, and a short time afterward I moved from that neighborhood. The patient then was nine or ten years old, and had begun to appreciate her condition. Last October she was brought to my office. Her parents had consented, if I still advised an operation, to have it performed at once. The patient was willing. She was then so annoyed and embarrassed that she preferred death to long life of this torture. She was now thirteen years old.

I made a thorough examination and concluded that her chances for a successful operation were less than when she was last seen, but there was still some hope of benefit if not of a cure.

I found the patient thin, pale, poorly nourished—ill in every sense of the term. Her condition was very distressing, and the parents were very apprehensive. I again advised an operation, and called Dr. Thomas R. Wright in consultation. After a careful examination he agreed with me.

At this time her condition was an extreme exaggeration of the first, and, while neither of us was very sanguine in regard to the result, we thought we could do little harm in case of failure, and if successful she would have a new lease on life.

Nothing new was revealed at this examination. There was only a small section of the sphincter of the urethra, about one-eighth of an inch long, but no vestige of the urethra. The labia minora had grown larger, more prominent, and were honeycombed in every direction by ulcers; the labia majora were longer, thinner, and much more widely separated at the top of the vulva. The intervening space was filled with mucous membrane. The V-shaped notch that extended through the mons veneris was wider; the transverse opening just under the pubic line was much enlarged. There was a small strip of bladder tissue lying just above the vagina, on either side of which the ureters emptied. The whole vulva was in a state of chronic inflammation, with ulcers scattered not only over the vulva but the whole of the lower limbs.

We could find but few cases of this peculiar defect; as a consequence our operation must be to a certain extent original. Several modes were discussed, only to be discarded as soon as analyzed. We finally decided on the following:

After due preparation we began by dissecting a two-thirds-circular flap out of the mucous membrane in front of and above the pubic bone. This dissection was two inches or more in diameter, and was from above the transverse cavity, continuing down on either side, and wide enough to form the urethra. This was continued down to the section of the sphincter muscle. The dissected flaps were brought together and closed in the usual way, down to the sphincter, through and around which we inserted one or more circular stitches. A glass tube was then inserted through the new-made urethra, and fastened with plaster, etc. Over the end of the glass tube was inserted a rubber tube (one yard in length), filled with water, for the purpose of producing gentle suction on the fluids that would accumulate in the new-formed bladder. This tube emptied into a vessel by the side of the bed, and succeeded nicely. All of this we supported by various forms of bandages and pads. This step in the operation was successful.

We now had the labia to close, the denuded surface to cover, and after dissection to support the new-formed tissue. This was done by carrying the dissection a little higher up in the V-shaped notch, paring the edges of the vulva, trimming the labia minora to normal size, and bringing the whole together with the usual form of stitches, except that we inserted one or two very stout sutures, deep and wide, to support the others. The parts were also protected with the usual form of pads and bandages. This step was also successful.

We began the first step in stretching the bladder by removing the rubber tube and using a cork in the glass one, which was removed every one and one-half or two hours for the passage of urine, and then replaced. During the whole of this time the tube had been duly removed, cleansed, and the bladder thoroughly irrigated with boric acid to prevent the accumulation always so troublesome in these cases. As soon as union was complete, we began to dilate with more energy, and found this the most difficult if not the most serious part of the procedure. This was to stretch or dilate the new-made bladder, which by this time was very much shrunken. We found it very difficult to get a support that was substantial and stationary. After trying various plans with only partial success, we took an oblong cork, cut a hole in the end of it, so as to fit the bottle end of a rubber nipple, which was tightly corked into the hole. The cork was then fashioned to fit the inside of the vulva and put proper pressure on the mouth of the urethra.

After padding with gauze an ordinary condom was stretched over the whole and tied in front and back. This end of the nipple was inserted into the vagina and the cork placed between the labia. We tried to support this with an ordinary T-bandage, but found it would not maintain uniform pressure. We then had a stout belt made, supported by whalebone to prevent wrinkling and to take the place of a T-bandage. To the back of this belt was fastened a four-inch rubber bandage. This rubber was split in front to below the vulva. By crossing these two ends in a certain manner, they gave support to both the cork and the outside of the vulva when fastened in front. When necessary to pass water she could detach the front part

of the bandage and replace it herself. The glass tube was dispensed with, of course, except for the purpose of washing out the bladder occasionally. Within the next three or four weeks with this support she was able to hold her urine from one and one-half to two hours. She has worn this support for about five months intermittently, and is able to hold her urine from three to four hours without it. She usually passes water from two to four times at night, and during the day about every four hours.

She now wears dry clothes day and night. But this is not all. She has undergone the most remarkable change. She is robust, well nourished, and is rapidly acquiring the development, both physical and mental, so long delayed with her. Not only are her parents delighted, but she is one of the happiest little girls in her section.

We look on this case as one above the usual interest, and if our experience shall be the means of helping some one else out of a similar bondage, we shall feel amply repaid.

Progress of Medical Science.

Uræmic Dyspnœa. — Five forms of dyspnœa have been described as occurring in uræmia, viz.: 1, Continuous; 2, paroxysmal; 3, both types alternating; 4, laryngeal; 5, Cheyne-Stokes breathing. The pathology of uræmic dyspnœa has been variously explained, *e.g.*, 1, contraction of the muscles of the smaller bronchi; 2, contraction of minute arterial twigs belonging to the coronary arteries or to the pulmonary vessels; 3, œdema of the lung or accumulation of fluid in the pleural sac; 4, anæmia; 5, cardiac debility and dilatation; 6, the influence of uræmic blood upon the terminations of the vagus nerve, or irritation of the motor fibres which supply the bronchial muscles; 7, direct irritation of the respiratory centre in the medulla by waste products in the blood.—TIRARD.

A Case of Congenital Malaria.—Dr. Winslow (*Boston Medical and Surgical Journal*, May 27, 1897) has reported the case of a male child, ten weeks old, apparently healthy and weighing seven pounds at birth, that did not flourish on its mother's milk and suffered from colic and vomiting. The child slept little, cried a great deal, was constantly moving, and had cold hands and feet. It had become emaciated, pallid, and weak. Various forms of artificial food had been employed, but without permanent benefit. The muscles of the limbs and neck were rigid, the head was slightly retracted, and handling induced crying. While under observation the little patient had a severe convulsion characterized by muscular rigidity, loss of consciousness, clonic spasms, and strabismus, followed by a period of muscular relaxation and stupor. It was now learned that similar attacks had taken place from birth, being always preceded by prolonged crying. The child became so ill that the prognosis was for a time doubtful. The question of malaria was suggested by the family, but, as the temperature had been normal and no periodicity of the symptoms had been observed, the matter was left in abeyance. The mother had had quotidian malaria of a severe type for two weeks preceding the birth of the patient, but treatment had been withheld on account of the existence of pregnancy. The symptoms disappeared at the end of labor. Improvement in the child's condition failing to take place in spite of varied treatment, examination of the blood was made, with the result of disclosing the presence of malarial plasmodia in abundance. The child was given one grain of quinine by enema twice daily, and the convulsions at once ceased, although the muscular rigidity, the sleeplessness, the colic, the constipation, and the restlessness persisted. After a month of such treatment the removal of the child to a non-malarial place was advised. Improvement at once set in, and after a week the quinine was withdrawn and one-fifth-minim doses of Fowler's solution were prescribed. The plasmodia disappeared from the blood, the child gained in weight, and in a short time was quite restored to health. The opinion is expressed that the plasmodia were probably conveyed directly by means of the fœtal circulation, although the possibility of infection through the mother's milk is not to be excluded. As the symptoms were the same up to the time that the diagnosis of malaria was made, it seems evident that the disease existed from birth.

Successful Removal of a Cystic Abdominal Tumor from a Child Aged Seven Months.—Dr. Campbell (*British Medical Journal*, May 15, 1897) has reported the case of a female child, seven months old, born with difficulty, the forceps being applied high up. The infant throve well and was apparently healthy at the age of three months, but about a month later the mother noticed swelling of the abdomen, which gradually increased. Periodic attacks of violent colicky pain also occurred. The general nutrition was good. The respirations were shallow and embarrassed. The abdomen was greatly distended by a lobulated tumor, which was more prominent on the left side, and felt hard in its upper half, but was soft and fluctuating below. There was dulness on percussion all over the abdomen except in the right hypochondriac region, which was resonant. Operation was decided upon, and under chloroform anæsthesia a median incision was made from midway between the ensiform cartilage and the navel to midway between the navel and the symphysis pubis. This exposed a large tumor lying behind the posterior parietal peritoneum and pushing the intestines into the right hypochondrium. The cystic portion having been tapped, the whole mass was enucleated from the subperitoneal tissue. No bleeding of consequence occurred, and no ligatures were needed. The tumor had no pedicle, but was more firmly attached deep in the left side of the pelvis than elsewhere. It lay in front of the left kidney, which was situated at the level of the iliac crest and was freely movable. The peritoneal covering of the tumor was attached to the edges of the lower end of the abdominal wound, and the cavity was packed with gauze. The upper end of the wound was closed by two layers of suture, silk being used for the peritoneum and silkworm gut for the skin and aponeurosis. The operation was well borne, except for a few seconds during the extraction of the tumor, when the pulse became bad, apparently owing to pressure on the cardiac area of the diaphragm. Two hours after the operation the child took milk and barley water, and was thenceforward fed every two hours. Fifteen-minim doses of whiskey were given every half-hour for the first three hours. The child slept well and vomited on one occasion only. On the sixth day the gauze packing was removed and the bowels acted spontaneously. On the eleventh day the silkworm-gut stitches were removed. The wound was then healed except where the drain had been. At the end of a fortnight the child went home. Three months later the silk stitches began to come away. Five months after the operation the child was in excellent health, though all of the silk had not separated. The tumor, which weighed three pounds when fresh, was found to consist of a cyst containing about ten ounces of clear yellow fluid, and of a solid portion in which a mass of cartilage and a piece of bone lay embedded. There was nothing to indicate the organ from which the formation originated.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, July 10, 1897.

THE BIOLOGICAL BASIS OF MENSTRUATION.

LITTLE is known concerning the phenomena of sexual physiology. The literature on it is very scant. Up to ten or fifteen years ago the universally accepted belief was that ovulation was the cause of menstruation, but a revolution in these views has taken place. Dr. De Sinéty in 1881 cast doubt on the old theory and since that time many have agreed with him, although now there is by no means unanimity of opinion among students on the subject. Various theories have been introduced as to the causation of menstruation, but as yet no definite conclusions have been reached. In a paper read before the Montreal Medico-Chirurgical Society and before the New York Academy of Medicine, Dr. Webster, of Montreal, puts forward the contradictory theories of different authorities, pointing out where he thinks they are wrong, and giving the result of his own observations. To Johnstone in America and to Heape in England much of the credit is due of demonstrating that ovulation is not the cause of menstruation. In this connection Heape examined the pelves of forty-two monkeys (Semnopithecus entellus) during their menstrual periods, and found evidences of ovulation being in progress in only two cases. According to Lawson Tait, removal of the Fallopian tubes, the ovaries being left *in situ*, is followed in ninety-five per cent. of cases by cessation of menstruation. Bland Sutton says, in direct contradiction of this statement, that "the Fallopian tubes exercise no influence on menstruation, and in order to produce artificial amenorrhœa both ovaries must be completely removed." In 1887 Johnstone disproved the long held idea that each menstruation results in the shedding of the entire endometrium, and defines the process of menstruation as a shedding of the superficial layers of the endometrium and as a kindred process to the moult in birds and the shedding of the horns and hair in the deer tribe. He has also advanced the theory, in which he is supported by Tait, that the menstrual act is a special function related to a distinct nervous mechanism. They think that possibly a special nerve trunk running in the upper part of the broad ligament may convey the regulating currents. Webster is inclined to regard the subject from a body metabolism and biological point of view, and thinks that the theory advanced by Geddes and Thomson in their "Evolution of Sex" is worthy of great consideration. This theory holds that the menstrual process is related to the balancing of anabolism and katabolism in the female. If the female sex be preponderatingly anabolic, menstruation is one of the functions of anabolism in the female and is a means of getting rid of the anabolic surplus. Looked at from a biological standpoint, the argument is as follows: Throughout the animal kingdom the distinctive and predominant characteristic of the male sex is katabolism and of the female anabolism. The same distinction is also found in the plant world, and these lines of inquiry are suggested thereby: 1. A study of sexual characteristics in the fully developed state and in the history of the individual. 2. An investigation into the condition of the lowest forms of animal and plant life in which sex has its beginning. 3. Observation of normal and pathological changes in the reproductive apparatus. 4. Experimental inquiry into the nature of the factors which determine sex.

Doubtless there is much opportunity for original research in studying this question from a biological standpoint, and it is possible that here the solution of the difficult problem will be found.

HYGIENE OF THE BARBER SHOP.

THE proposition to make a more careful man of the tonsorial artist, in so far as relates to the transmission of disease from his infected to his well clients, is not a new one. The subject has been written upon by several earnest men before Heinrich Berger, whose "Hygiene in den Barbierstuben" recently appeared in Leipzig. No writer has, however, seemed to go so deeply into the question and lay down such strict rules for the knight of the shaving-knife. We are told that he must be a person free from epilepsy and all manner of seizures, drunkenness, and infectious diseases.

Being free from these affections himself he may give professional attention to all persons, including those under the influence, or those likely to have a fit in the chair, provided they are free from skin, hair, and sexual diseases of an infectious nature. Otherwise they are to be treated at home with their own implements. The author gives a number of other rules which are in themselves and, so far as they go, good—if barbers could be prevailed upon to follow them—but he does not sufficiently insist upon the necessity of boiling to the point of sterilization his instruments, towels, sponges, and especially his own hands.

There are many things besides the so-called barber's itch which may be transmitted in uncleanly shaving and hair dressing, and of which the public knows little or nothing. Favus is decidedly on the increase in this country, and the number of children turned away from the cities' schools for this cause since the inspection innovation went into effect would greatly surprise those who think of favus as a European or foreign affection.

Syphilis is undoubtedly transmitted now and then, through the medium of the barber's armamentarium.

Attention has recently been called by a member of the New York Dermatological Society (*Journal of Cutaneous and Genito-Urinary Diseases*) to the danger of the epilating tweezers used in barber shops. Ingrowing hairs and those attended by suppurative inflammation, as in sycosis, are extracted, and the next comer is operated upon without adequate and usually without any cleansing at all of the instrument. In one instance reported, a chancre of the cheek was attributed to the use of such an instrument, which had probably not been cleaned after being used upon a syphilitic subject. Certain rules should be adopted, if possible, by barbers in general, to protect their patrons from dangers which are more real than imaginary. Above all, they should remember that scrupulous cleanliness of implements and hands is the first requisite, and the advice now being given to surgeons to "boil their hands" applies almost equally to them. At the least they could give a little wash between each "next," for the mere sake of appearances and in the interest of business if for nothing else.

THE EFFECT OF THE DISPENSARY SYSTEM IN LONDON.

In reference to the controversy on the question of the abuses of dispensaries now in progress in this city, it may be instructive to take London as an object lesson and to sketch briefly the effect of the dispensary system there. In London there have been free dispensaries for more than one hundred years, and so long as the system was restricted to free dispensaries and properly supervised it was of great benefit to the poor. Since the introduction, however, of self-supporting dispensaries, some twenty years ago, this happy condition has been totally changed. The truth is now acknowledged on all sides that the self-supporting dispensary system has been a prominent factor in the reduction of medical fees throughout the kingdom. That they were introduced with the laudable object of helping the poor and of fostering in them a spirit of independence is probable, but unfortunately the result has been exactly the opposite. From their inception abuses crept in, and have continued to creep in. Charity was the object of the old free dispensaries; money making appears to be that of the provident. The principle of these dispensaries is nothing more in too many cases than cheap physic. The large class for which they were designed, that between the pauper and the small tradesman, join only in small numbers; on the other hand, the small tradesman and respectable mechanic, who can afford to pay a small medical bill, are supporters of the dispensary, and both the doctor and the patient are sufferers—the doctor in his pocket, and the patient in his self-respect.

These dispensaries have been wholesale propagators of pauperism. Through their means, too, in London and in the other large towns in Great Britain, the cash practice has been introduced, with the consequent irremediable reduction of medical fees. The practitioners in the districts in which provident dispensaries were introduced, in order to compete with them, were compelled in sheer self-defence to build up a clientèle by somewhat similar means, or at any rate to give advice and medicine at an equally low rate. John Stuart Mill said: "There are kinds of labor of which the wages are fixed by custom and not by competition. Such are the fees or charges of professional persons, of physicians, surgeons, barristers, and attorneys. These, as a rule, do not vary; and although competition operates upon these classes as much as upon any others, it is by dividing the business and not by diminishing the rate at which it is paid." When these words were written they were true, but if Mill were alive now what a change he would see, when there is as much cutting among medical men as among tradesmen. Forty years ago in England those who could pay for medical services paid a fee of about a dollar and a half, and for those who could not afford so much there were the clubs and parish doctors. Now the pleasing spectacle is to be seen of highly educated men, graduates of Oxford or Cambridge, selling their skill and medicine for twenty-five cents, and others underselling them at twelve or eight cents. In the last forty years a lowering of the charges for medical services has gone on *pari passu* with the raising of the standard of medical education, so that at this moment medical men in England are probably the best educated and worst paid of any of the professions.

The foregoing is a true account of the manner in which the development of the dispensary system has acted on the medical profession in England. The effect on the general public is just as disastrous; the number of people who seek the aid of medical charity in London is simply appalling.

THE SPITTING NUISANCE.

The arrest and fine of an influential and defiant spitter in one of the street cars of San Francisco is a striking means of educating the public in matters of health and decency. Considering the few offenders who are punished, and the vast number of transgressors who escape, there is a great deal of missionary work to be accomplished. In our own model city, where the antispitting boom took its first bound into favor, the nuisance of promiscuous spitting is almost as bad as ever. The health-board notices do no good whatever. If more arrests were made, it would bring the matter of violation of the ordinance most directly and most forcibly to the attention of the people. A good way to start an efficient crusade against the spitters would be a detail of policemen in citizen's clothes, who should disperse on certain car lines and should immediately arrest every offender caught in the act. One officer in one car of each of the different companies could make a record which would astonish the public and create a proper sentiment accordingly. There is no reason also, for the convenience of such invalids as must expectorate, that properly disinfected cuspidors should not be provided in some out-of-the-way corner of the conveyance, or in the larger cars that some spitting closet should not be set apart for

the spitters. The trouble of getting up to expectorate would oftentimes as effectually settle the question to spit or not to spit, as it would to choose or not the back of the neck of a standing passenger in a packed cable car.

THE PATHOLOGY OF THE DIARRHŒAL DISORDERS OF CHILDHOOD.

From an extended clinical and pathological study at the Kaiser and Kaiserin Friedrich Kinderkrankenhaus in Berlin, Baginsky (*Archiv für Kinderheilkunde*, Bd. xxii., H. 3–6) concludes that the diarrhœal disorders of childhood arising under the influence of high summer temperature are at first only functional in character, consisting in changes in the motor and secretory functions of the gastro-intestinal tract, with abnormal digestive chemism. In their further course profound anatomical alterations take place in the walls of the stomach and bowels, which may range between catarrh and necrosis of the mucous membrane. The follicular changes are processes of peculiar character and independent of the catarrhal, with which they may in the course of time be associated. They lead sometimes, in addition to superficial changes, also to ulceration. These changes are attributable not to specific bacteria, but to the ordinary saprophytic micro-organisms of the intestinal tract that assume especial virulence. Under peculiar circumstances other bacteria not ordinarily found in the intestinal tract may act as causes of diarrhœal disorders. These also induce profound anatomical changes in the walls of the bowel. The invasion of other organs by these bacteria is not unusual, but is rather relatively common with regard to the kidneys. Under these circumstances the bacteria may cause profound anatomical lesions, even to the extent of suppuration. The transmission does not usually take place through the blood stream, the bacteria being but rarely found in the blood, and then only in small numbers. The most profound disturbances are occasioned by the fermentative products of bacterial activity, toxic or non-toxic. These are either of the nature of acids or products of albuminous degeneration, down to ammonia and its combinations, which behave as active irritants and thus cause injury to the walls of the bowel. Further, through the blood current and the lymph stream they exert a degenerative influence upon other organs, especially those possessed of excretory functions, such as the liver, the kidneys, etc. Under the influence of this intoxication from the intestinal tract the resistance of the whole organism to the invasion of other pathogenic micro-organisms is diminished, as is manifested by numerous complications.

The Medical League, whose worthy aim is to suppress the glaring abuse of dispensary and hospital charity, is growing. It has recently established a branch in Brooklyn and gives promise of keeping up its aggressive warfare until the enemy is routed, and the dispensing of charity is confined within proper and decent limits.

News of the Week.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending July 3, 1897. July 1st.—Assistant Surgeon J. F. Leys detached from the *Vermont*, July 6th, and ordered to the *Helena*, July 7th. Assistant Surgeon C. E. Riggs ordered to the *Vermont*, July 6th.

The Tri-State Medical Association of Western Maryland, Western Pennsylvania, and West Virginia will meet at Bedford Springs Hotel, Bedford, Pa., on Thursday, July 15, 1897. An attractive programme is promised.

A Congress of Colored Physicians has been called to meet in Washington on July 21st–23d. The object of the promoters of the meeting is to form a National Medical Association of Colored Physicians. But "it is not the aim of the association to conflict with white conventions of physicians, nor to decrease the interest of colored physicians in those white organizations to which they may belong; it is simply wanted for a promotion of fraternal interest among the colored professional men." It is estimated that there are about two thousand colored physicians in regular practice in the country. Dr. John P. Golden, of Allegheny, Pa., is one of the originators of the movement.

Paul F. Mundé, M.D., LL.D.—At its recent commencement, it being also the centenary of the medical school, Dartmouth College conferred the honorary degree of LL.D. on Dr. Paul F. Mundé.

The British Medical Temperance Association.—At the recent annual meeting of this association, the president, Dr. Sims Woodhead, in his inaugural address, pointed out how medical men had influenced the temperance movement. He referred to the pathological degradation observed after the ingestion of repeated moderate quantities of alcohol, and commended the work of the Society for the Study of Inebriety and the British Medical Temperance Association as worthy the support of the members of the profession. The membership of the association is now four hundred and fifty-three.

Prof. W. T. Engelmann, of the University of Utrecht, has been called to the chair of physiology at Berlin rendered vacant by the death of Dubois-Reymond.

Plague (?) in Constantinople.—A report from Sofia says that Bulgaria has established a two-weeks' quarantine against travellers from Turkey, because of an outbreak of the plague at Constantinople.

College of Physicians of Philadelphia.—At the concluding meeting for the season of the section on general medicine of the College of Physicians of Philadelphia, on June 14th, Dr. H. A. Hare read a communication on "The Value of the Various Preparations of Digitalis," and Dr. J. C. Wilson "A Brief Statistical Paper on Enteric Fever Based upon One Hundred and Fifty Hospital Cases."

Dr. Henry C. Coe has been appointed to the new chair of gynæcology at Bellevue Hospital Medical College.

"The Pittsburg Medical Review," having been made the official organ of the Medical Society of the State of Pennsylvania, has become *The Pennsylvania Medical Journal.* The new journal, like the old, will continue to be published in Pittsburg. The greatest good that we can wish the journal under its new name is that it will be the equal in excellence of its former self.

A Disastrous Fire.—Shortly after the close of a brilliant reception given some time ago at the house of Dr. B. Sherwood Dunn, in Los Angeles, fire broke out, and before the department could respond and get a stream upon the flames the entire structure was consumed, together with its contents, including many valuable paintings, bronzes, and tapestries collected by Dr. Dunn during his residence in Paris.

International Deaf-Mute Congress.—A convention of educators of deaf-mutes is to be held in Glasgow on July 28th–31st, and will be immediately followed by an international congress of deaf-mutes in London, August 3d–9th.

Tuberculin in France.—According to French law the sale of serums is authorized only after the Academy of Medicine has given its approval to samples and inspected the laboratories where they are prepared. This law was passed to prevent all sorts of serums being put forward by druggists without any guarantee of asepsis or strength. Very few laboratories obtain the necessary certificate. Koch's tuberculin, the Paris correspondent of *The Lancet* writes, to have the right of entry in France for sale, has had to undergo the judgment of the academy, based upon the report of M. Nocard, the assistant director of the Pasteur Institute. The report commenced by saying that any French product produced under circumstances precluding the academy from any surveillance as regards the conditions of its manufacture would certainly be refused. The sample sent in amounted to one cubic centimetre, enough for only one experiment, and the liquid was turbid and full of bacteria and yeast fungi. The bacteria were very possibly not pathogenic; but their presence was not reassuring, for it would appear to show that the liquid was not prepared under aseptic conditions, and even if the organisms did no harm to the patient they would probably weaken the power of the serum. The academy, fearing that a refusal of the authorization would be attributed to national jealousy, has authorized the introduction of the lymph provisionally, despite the report of M. Nocard. Many of the papers have published articles expressing regret at this decision.

Obituary Notes.—Dr. Ira B. Read, of this city, died of pulmonary tuberculosis on July 4th. He was born at Norwalk, Ohio, and was a graduate of the University of Michigan in 1867, and of the Bellevue Hospital Medical College in 1868.—Dr. McD. M. Powell, of Collinsville, Ill., shot himself on June 20th. He was thirty-four years old, and was a graduate of the St. Louis Medical College in 1886.—Dr. James Cavanaugh died at Easton, Pa., on June 28th, at the age of sixty-seven years. He was graduated from the medical department of the University of Pennsylvania, in 1850, and was at the time of his death president of the local United States pension examining board. He was for many years physician to the Northampton County prison and surgeon to the Central Railroad of New Jersey.—Dr. W. H. H. Hutton, of the Marine Hospital service, died on June 14th. He was born in York, Ohio, in 1838. He served in the union army during the civil war. He attended his first course of medical lectures at the Alabama Medical College, at Mobile, and on March 16, 1875, was graduated from the Chicago Medical College, Chicago, Ill., receiving from this institution the first prize of the faculty for the best graduating thesis. He was appointed assistant surgeon in the Marine Hospital service, in 1875, and was promoted to the grade of surgeon the following year. During his connection with the Marine Hospital service, he served as commanding officer at the stations of New York, Cincinnati, New Orleans, Detroit, Louisville, Mobile, and Baltimore. In addition to the above duties he rendered valuable service at Brunswick and Way Cross, Ga., and Camp Perry, Fla., in 1888, in enforcing the quarantine and other measures during the yellow-fever epidemic of that year, and again at Brunswick, Ga., during the yellow-fever epidemic in 1893. At Camp Perry he installed and was in command of the first detention camp, which proved so successful in the management of the epidemic at that time raging in Jacksonville. He was also in charge of the quarantine establishment at Sandy Hook, N. J., during the cholera scare in 1892, and later in the same year rendered efficient services in the establishment of the quarantine flotilla at Cape Charles.—Dr. Richard Smith Bacon, for many years head master of the Columbia Grammar School, died at his home in this city on July 6th. He was a graduate of the College of Physicians and Surgeons in this city, but practised medicine only about a year.—Dr. John B. Carpenter died June 17, 1897, at Groveton, N. H., aged thirty-five years. He was a graduate of Buffalo Medical College in the class of 1893. He practised two years in Washington, D. C., and two years in Groveton. He was a member of the Medical Association of the District of Columbia, and also a member of the New Hampshire Medical Society.

Epidemic Ophthalmia.—It is reported from Hamburg that granular ophthalmitis prevails there to an alarming extent among the school children.

Trouble at the Collins State Hospital.—It is reported that the selection of Dr. Daniel H. Arthur, of Middletown, as superintendent of the Collins State Homœopathic Hospital of Erie County, by the board of managers of that institution, to succeed Dr. G. Allen, will not be recognized by the State lunacy commission until the courts have passed upon the legality of the action taken by the local board in dismissing Dr. Allen. The matter must be taken to the courts very soon, as the Collins Hospital cannot be

run without money obtained through the lunacy commission. Dr. Allen has engaged counsel and will contest the right of the managers to remove him. The newly appointed superintendent is enjoying a leave of absence until the question of his legal existence as a superintendent is determined.

The American Medical Temperance Association held a meeting on July 5th, at Prohibition Park, Staten Island, under the presidency of Dr. T. D. Crothers. Most of the speakers held that the use of alcohol in medical practice is not only unnecessary but harmful. One of them was reported, we trust incorrectly, to have said that one grain of wheat contained more nutrition than a keg of beer. It is regrettable, for the sake of the cause which they advocate, that so many temperance orators say, or are reported to say, things that are absurd and untrue.

The Late Dr. J. Lewis Smith.—It is with sorrow that we record in the minutes of the faculty of the Bellevue Hospital Medical College, the death on June 9, 1897, of Dr. J. Lewis Smith, late clinical professor of diseases of children. Dr. Smith was a teacher in the college for thirty years. He brought to his instruction a ripe experience and sound judgment, and had attained a most enviable reputation, not only as a public teacher but as a voluminous writer on the subjects of his special studies. His loss will be deeply felt, not only by the profession but by the public at large, who benefited so much by his skill and devotion. AUSTIN FLINT, *Secretary.*

Cheating at State Medical Examinations.—From the State of Pennsylvania comes the report that in connection with the recent examinations held in Philadelphia of applicants for license to practise medicine unsuccessful attempts were made to secure in advance by subterfuge copies of the questions that were to be put. One of the applicants was not permitted to conclude his examination on account of being detected in the possession of printed questions which had been secured for the purpose of illegitimate aid.

The Dispensary Abuse in Pennsylvania.—The medical board of each of the three hospitals of Reading, Pa., has appointed a committee of three "for the purpose of formulating a code of rules under which the pecuniary interests of the medical profession can be protected without prejudice to the deserving poor." Among other things it is alleged that "persons in well-to-do circumstances are in the habit of accepting medical and surgical services at our charitable institutions free of charge."

J. M. Da Costa, M.D., LL.D.—At the annual commencement of Harvard University, on June 23d, the honorary degree of doctor of laws was conferred upon Dr. J. M. Da Costa, of Philadelphia.

Chautauqua County (N. Y.) Medical Society.—The annual meeting of the Chautauqua County Medical Society will be held at Chautauqua Assembly, Tuesday, July 13, 1897, and will be called to order at 11 o'clock A.M. The annual election and other routine business will be transacted, including the voting upon the amendment to the constitution relative to the time of holding the semi-annual meeting. The president is Dr. E. S. Rich, of Kennedy, and the secretary Dr. C. A. Ellis, of Sherman.

Examinations for the Army Medical Corps.—An army medical board will be in session at Washington City, D. C., during October, 1897, for the examination of candidates for appointment to the medical corps of the United States army, to fill the five existing vacancies. Persons desiring to present themselves for examination by the board will make application to the secretary of war, before September 1, 1897, for the necessary invitation, giving the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from which they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal acquaintance, from at least two reputable persons, as to his citizenship, character, and habits. The candidate must be between twenty-two and twenty-nine years of age, and a graduate from a regular medical college, as evidence of which his diploma must be submitted to the board. Successful candidates at the coming examination will be given a course of instruction at the next session of the Army Medical School, beginning November 1, 1897. Further information regarding the examinations may be obtained by addressing Dr. George M. Sternberg, Surgeon-General, United States Army, Washington, D. C.

The Senn Surgical Prize.—A medal, to be known as the Nicholas Senn prize medal, will be awarded at the annual meeting in 1898, to that member of the American Medical Association who shall present the best essay upon some surgical subject. Two other essays, if any are worthy, will receive honorable mention. The conditions of the competition are as follows: 1. The name of the author of each competing essay shall be inclosed in a sealed envelope bearing a suitable motto or device, the essay itself bearing the same motto or device; the title of the successful essay and the motto or device to be read at the meeting at which the award is made, and the corresponding envelope to be then and there opened and the name of the successful author announced. 2. All successful essays become the property of the association. 3. The competition is to be confined to those who at the time of entering the competition, as well as at the time of conferring the medal, shall be members of the American Medical Association. 4. The competition will be closed three months before the next annual meeting of the American Medical Association, and no essays will be received after March 1, 1898. Competitors will address their essays to Dr. J. McFadden Gaston, 1½ Edgewood Avenue, Atlanta, Ga.

Some Colored Scalawags, who swindled a number of medical men in this town last year by soliciting alms for the support of an alleged school in Virginia, have at last come to grief. They approached a num-

ber of clergymen, who are more conversant with wickedness of that sort than the innocent and guileless doctor, with the result of falling into the hands of the police.

Mississippi Department of Public Health.—A bill has recently passed the Mississippi legislature providing "that the Mississippi State Medical Association and all other State, district, and county medical societies and associations of the State in affiliation with the purposes of its organization, are hereby constituted the 'Mississippi Department of Public Health' and any licensed practitioner of medicine in the State of Mississippi, who is a graduate of an approved institution of medicine, may on application have his name enrolled as a member of said department." The duties of this department are, through its committees, to exercise a general superintendence over the health interests of the State, the collection of vital statistics, and the development of medical literature; to prescribe rules and regulations, with a specification of duties, for the conduct and reports of said committees; to investigate and report upon the hospitals, asylums, and other like institutions in the State; to take cognizance of and make recommendations for the interest of health and life among the people generally; to investigate the causes, means of prevention, and treatment of endemic and epidemic diseases; to investigate the influences of localities and employments upon the public health; and to act as an advisory board to the State in all hygienic and medical matters.

A Medical Mayor.—Dr. M. Gibson Porter, a graduate of the University of Maryland, has been elected the second time as mayor of the town of Lonaconing, Md.

The Superintendent of the Molokai Leper Colony, Mr. H. R. Meyer, died recently of heart disease. He was a resident of the island at the time the colony was established, and was its superintendent for many years.

The Chalfont Epileptic Colony.—Mr. Bayard, recently United States ambassador at the Court of St. James, laid the foundation stone of the new Home for Men, presented by Mr. Passmore Edwards to the National Society for the Employment of Epileptics at the Colony Chalfont, St. Peter, Bucks, on Thursday, May 6th, at three o'clock. Mrs. Bayard opened the Home for Women at the colony, also the gift of Mr. Edwards, on the same day.

Jefferson Medical College.—A scientific meeting of the Philadelphia Chapter of the Alumni Association of the Jefferson Medical College was held in the college building on May 10th. Dr. John Lindsay read a paper on "The Treatment of Acute Anterior Urethritis in the Male," in the discussion of which Drs. J. Chalmers Da Costa and Orville Horwitz took part. Dr. Addinell Hewson was elected *President;* Dr. J. L. Salinger, *Corresponding Secretary;* Dr. W. M. Sweet, *Recording Secretary;* and Dr. J. A. Cantrell, *Treasurer.*

Baltimore County Medical Society.—The physicians of Baltimore County, Md., have formed a County Medical Society, and it is expected that such societies will be formed in the other counties not already having them.

An Accusation against Harvard.—Mr. Moody, the evangelist, is reported by the daily press to have asserted, in the course of an address in Boston, that Harvard University, the Medical Department in particular, is a sink of moral iniquity. As well might one say that the Methodist Church is a hotbed of immorality because a Methodist minister was dismissed from his pastorate a few days ago for the reason that he was the father of his servant's infant. Mr. Moody is not the only one who seems to think the cause of religion can be helped by intemperate statements, the exaggeration in which borders very closely on the deliberately spoken untruth.

A Great Man Gone.—A most successful maker of quack medicines in Berlin recently committed suicide while suffering from religious mania. His income from the sale of his remedies was estimated at over $50,000 a year.

Private Hospitals in Berlin are threatened in their existence by the new regulations issued by the Prussian government. According to these, no building used in whole or in part as a hospital can have a courtyard enclosed on all four sides; the corridors in all hospitals must be at least 1.8 metres (five feet ten inches) in width, the staircase must be of a certain width, and the steps of a certain prescribed height, and no room with none but north windows can be occupied by patients. These and other regulations, if strictly enforced, will make it impossible to use any apartment for private hospitals, and those surgeons who wish to maintain those they now have will be forced to erect special buildings—a serious matter in Berlin, where land is very expensive.

English Bacteriologists are apparently held in as slight esteem by the government of Cape Colony as English ophthalmologists are by Queen Victoria. Koch was hired to go there to study the rinderpest, and now Kolle, of the Berlin Institute for Infectious Diseases, has received a year's leave, says the *Medical Times*, in order to proceed to Cape Colony, where he has been commissioned by the Cape Government to carry on the work of Professor Koch. He will continue the investigation into rinderpest and leprosy, and organize stations for the study of those diseases.

The Maryland Homœopathic Hospital in Baltimore is to be rebuilt on the site of its present building, which is much too small to accommodate all the applicants for admission. The proposed building is to be five stories high, with a basement, and a frontage of one hundred and fifty feet by a depth of sixty. The cost will be from $80,000 to $100,000, and will be raised by subscripion, as the institution is wholly a charitable one. During the past year there were five hundred patients treated at the hospital, and fourteen thousand prescriptions were put up.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

SECTION ON PRACTICE OF MEDICINE.

J. H. MUSSER, M.D., PHILADELPHIA, CHAIRMAN.

(Continued from page 2.)

Thursday, June 3d—Morning Session.

The Application of the Roentgen Rays to Medical Diagnosis.—DR. C. L. LEONARD, of Philadelphia, was the author. The chief advantage of the radiographic method over previous methods was in the fact that it formed real images, whereas only mental pictures existed before; it eliminated the personal equation of the observer from the question of diagnosis. The radiographs could be retained for comparison with others of similar conditions. The application in medicine was considerably different from that in surgery. The results thus far had not been so brilliant, but the field promised to be even greater than in surgery. The author showed radiographs of certain diseased conditions in the thorax, abdomen, and pelvis. It was of value in outlining aneurism of the aorta. In one case it showed that the subclavian could be ligated at the point of election for an existing aneurism without involving the tumor. In a case of dilatation of the heart the walls were so thin that the light penetrated them easily. In a case of dilatation of the stomach the organ was washed out and a solution of bismuth salts injected, lining the interior of the cavity; the shadow cast by these salts was deeper than that of the pelvic walls, thus enabling an observer to map out the area of the stomach. In a case of fluid in the peritoneum, this was shown by deeper shadow, the shadow changing its position with the movement of the fluid. In the same case a button was supposed to be in the stomach, but its absence was proven.

Tuberculosis Antitoxin.—DR. E. A. DE SCHWEINITZ, of Washington, gave a *résumé* of experiments made in the production of a tuberculosis antitoxin. Briefly, such a substance could be produced, though in small amount, which would protect an animal from a fatal dose of tuberculin or which would retard a fatal issue from the usual time of three or four weeks to ten or twelve weeks. If he might judge from his own results and a study of those obtained abroad, it was possible that an antitoxin could be produced for tuberculosis, but treatment by this method was still in the experimental stage and would probably remain so until it became possible to protect guinea-pigs against tuberculosis and cure them when infected, as was done in the case of diphtheria with diphtheritic antitoxin.

Antituberculin.—DR. J. MCFARLAND, of Philadelphia, said his paper contained the results of experiments similar to those of the last reader, only he had devoted more attention to antituberculin. He first gave reasons for his belief, entertained from the first, that tuberculin must fail. Among these was the pathological fact that tuberculosis was an inflammatory, not a toxic condition. Many cases progressed to the extent of producing considerable destruction of organs before constitutional conditions manifested themselves. Finally, when the tuberculous nodes began to disintegrate, other germs appeared. The reader disclaimed originality in the use of antituberculin, mentioning the work of Paul Paquin and others. It was not irrational to suppose that it might add to the resistance of the tissues, or prevent breaking down of those in which the tubercle bacilli were encapsulated, thus limiting their spread to others. In doing this it would slow the pulse, stop hectic, etc. The animals which he had experimented upon had not recovered, but life seemed to have been prolonged. Moreover, guinea-pigs, it was to be remembered, were extremely susceptible to tuberculosis, and because an agent might not be altogether successful in them it did not prove that it would not be in man. The guinea-pigs on which he had practised immunization longest were still alive, but he could not say that they had not tuberculosis, since there were enlarged glands. He had found the tuberculin harmless in both healthy and tuberculous guinea-pigs. In man the remedy had been applied systematically in about twenty cases. He thought one could be reported as cured, one as very encouraging, one as distinctly better, three decidedly improved, five improved somewhat, seven not definitely changed, two worse; three subjects had died, but not because of the treatment. Urticaria was almost uniformly present, which might be accounted for by the fact that serum of the ass was used, which was more irritating than that of the horse. There was some pain in the back and jaw.

A Report on Treatment of Tuberculosis.—DR. D. L. ROCHESTER, of Buffalo, gave some experience with different methods of treatment of tuberculosis, including the use of Paquin's tuberculous antitoxin, Vaughan's nuclein, and Edson's aseptolin. When criticised for mentioning the latter he said he had used it soon after the paper describing it was first published and at the request of the patients themselves. The number of cases treated with it was nine, with four deaths, one, he thought, as a result of the agent used. In no case could he report a cure, and when improvement had taken place it could be attributed to other factors, especially that of living out of doors. Paul Paquin's tuberculous antitoxin was of no value when phthisis was at all advanced, and he had been compelled to discontinue it by the patients themselves, because of dermatitis and pain. As to Vaughan's nuclein, it had been a benefit in all cases but one. It did no harm if the injections were not too rapidly increased. One patient recovered, although there was a cavity at the beginning of the treatment two years ago. Yet without exercise and fresh air all efforts must count for naught. The author considered treatment of special symptoms, cough, anæmia, etc.

A Further Report on the Treatment of Tuberculosis by Iodoform Inunctions.—DR. L. F. FLICK, of Philadelphia, referred in this paper to one which he had read before the Philadelphia County Medical Society, on the use of iodoform inunctions in tuberculosis, he having begun its use about eight years ago. The conclusions drawn from over one hundred cases were that it was unsafe to form an opinion of a treatment of tuberculosis within a short time after its commencement. Unless the case had stood the test of a cure a number of years it could not be placed among the cures. He was now compelled to report many of his patients as dead whom he had reported cured two or four years ago. Mere increase in weight and improvement in symptoms were no evidence of permanent cure of tuberculosis. In his earlier cases he must report at least eighty per cent. mortality to-day.

DR. S. SOLIS COHEN discussed the several papers. He could not agree with the last reader that a remedy could not be said to have cured tuberculosis should the patient die years afterward. There might be reinfection. Then a remedy might be of great value in causing improvement, prolonging life, and checking the active process of the disease.

Thursday, June 3d—Afternoon Session.

Curability of Pulmonary Tuberculosis.—DR. E. B. BORLAND, of Pittsburg, read a paper on this subject. Evidence was accumulating which went to show that tuberculosis was not only a universal disease but the

universal disease. Twenty-five per cent. was much too low an estimate of the total number of infections. The author quoted autopsy statistics from which he concluded that fully fifty per cent. of the people were infected at some period of life, two-thirds of them with the pulmonary form. Now, since the total death rate gave only fourteen per cent. as due to tuberculosis, it became evident that the disease was not so very fatal. There must be many spontaneous cures. Not a single antitoxin having been discovered to cure the affection, the physician would do well to make the best use of older methods. Tuberculosis uncomplicated by sepsis could be considered a curable disease in the sense of being held in abeyance, provided the vital resistance of the individual were kept up to the normal standard. Nature had been known completely to eradicate tuberculosis in a number of instances. Nothing could prevent infection when three conditions were present—debility, abrasions, tubercle bacilli.

Dr. Denison, of Denver, approved of the work of de Schweinitz, McFarland, Trudeau, Klebs, and others in searching for a tuberculin or an antituberculin. He himself had been accused of getting results during trials with some of these which it was claimed were due to the influence of climate. Still he approved of such researches.

Dr. Klebs, of Citronella, thought it would be a dangerous conclusion to infer that experiments with tuberculin, etc., made in laboratories were without value, and that we must limit ourselves to clinical observations, for it would stop scientific research. Tuberculosis was so various in its manifestations that long observations in experimental research were neces sary to establish the value of a remedy against it. Dr. Klebs thought the State should erect institutions for the treatment of tuberculous patients, as in them they could best be taught to carry out hygienic measures, proper disposal of the sputa, etc.

Dr. Herrick, of Cleveland, could not accept fully the idea of tuberculosis being due to infection, but was inclined to regard it rather as a disease due to disturbances of the blood-making processes. He should never look for a specific agent against tuberculosis. We must go back to the physiological principle in treatment and prevention.

Dr. Sternberg expressed his surprise at hearing a doctor speak to-day with doubt regarding the infectiousness of tuberculosis. He then briefly gave the proofs of infection by tubercle bacillus.

Others who discussed the papers on tuberculosis were Drs. Alten, of Kansas City, Upshur, of Richmond, Tyson, Paul Paquin.

Some Deformities of the Chest in the Light of Its Ancestry and Development.—Dr. Woods Hutchinson, of Buffalo, spoke on this subject. There were two forms of chest: 1, the quadrupedal, in which there was great antero-posterior development; 2, the chest in which the lateral expansion seemed to have gone on at the expense of the antero-posterior development. The former existed in dogs and lower animals with the exception of the bat. As one approached man the lateral expansion became greater. Dr. Hutchinson explained the development of the chest of lateral expansion by man and his nearer ancestry assuming the upright position and swinging by the arms. Taking 100 as the basis, the following index was given: Proportion of depth to breadth of chest in man, 71; dog, 125; fœtus, 103; infant, 87; tuberculous chest, 77. The index for length was also given. In chests showing a tendency to become diseased, especially with tuberculosis, we saw a narrow chest, one showing a tendency toward the ancestral type. He had at one time accepted without investigation the notion of a flat chest in tuberculous patients, but on investigation had found that this flatness was always, or nearly always, only seeming; that there was in reality less breadth than normal, and the apparent flatness was due, he thought, to lack of flat surface on which the shoulders could rest, these rolling forward and giving a hollow appearance across the chest. Reversion to the primitive type in circumstances not suitable to it was the starting-point for disease. The explanation of the fact that the lung was the organ most frequently attacked by disease, especially by tuberculosis, was that in the light of ancestral development it was the youngest organ of the body.

Management and Treatment of Malignant Types of Croupous Pneumonia.—Dr. D. S. Campbell, of Detroit, discussed in a general way the treatment of croupous pneumonia, dividing the cases into two classes—the mild ones which required little treatment, and the severer ones in which there was high fever with tendency to heart paralysis. It was in the latter that he had found cold the most valuable heart stimulant and antipyretic. Cold applications were usually indicated, but in very obstinate cases the cold bath should be employed.

Dr. H. O. West, of Galveston, thought the author had emphasized too strongly the purely mechanical effects of pneumonia and the fever element, and had overlooked the toxic influence.

The Hot Bath in the Treatment of Pneumonia.—Dr. J. Eichberg, of Cincinnati, read a paper in which he praised highly the effects of the hot bath used systematically in the treatment of pneumonia. At first he had used it as an antipyretic, repeating it only when the temperature rose above 103° F., but subsequently repeated it every three hours, regardless of the temperature. It had a marked influence on the nervous symptoms, one of which was undefinable unrest, which it caused to disappear; the pulse improved, delirium subsided, the respirations diminished; the patient was enabled to sleep. The temperature of the bath was from 90° to 110° F., according to circumstances; it was continued ten minutes.

Cheyne-Stokes Respiration.—Dr. N. S. Davis, Jr., of Chicago, read a paper on this subject, describing characteristic Cheyne-Stokes respiration, mentioning errors in diagnosis, then referring to treatment. He had found much literature on the subject, principally theorization regarding the cause, and little as to treatment. In chronic cases with weariness of respiration this was important, yet his own success seemed not to have been great, and he had tried various drugs, such as nitrites, strychnine, etc. The latter, strychnine, had given him very little result. Cheyne-Stokes respiration occurred at times in various maladies, but most frequently in uræmia and cerebral affections. It had also been produced experimentally. Its exact nature was unknown. Undoubtedly the best treatment was that directed against the maladies causing it.

Multiple Neuritis Following Influenza.—Dr. H. B. Allyn, of Philadelphia, expressed the opinion in this paper that influenza was not an infrequent cause of neuritis, sometimes of multiple neuritis. Personally he had seen more cases of neuritis in influenza the past year than in the previous five years, and more in mild cases of influenza than in severe ones. It was probable that some cases of supposed neuralgia were cases of a moderate degree of neuritis.

A Case of Acute Lymphatic Leukæmia with Streptococcus Infection.—Dr. J. B. Herrick, of Chicago, reported the case. The patient was a saloon keeper, twenty-seven years of age, who had been quite well a few weeks before Dr. Herrick saw him; he was then under the care of a physician who stated that he first had a sharp attack of sore throat, with recurrence after a week, and then rapid enlargement of the glands of the neck, axilla, and groin. The spleen was enlarged. He was under Dr. Herrick's observation only three

days before death. Besides lymphatic enlargements and increase in the size of the spleen, there were numerous retinal hemorrhages, pallor of skin and mucous membranes, hemorrhagic tendency particularly marked in the nose, and malaise. The blood was examined once, and showed great increase in the white cells compared with the red. Streptococci were found, and the question arose whether the acute leukæmia was due to streptococcus infection in the throat. It seemed quite certain that leukæmia had not existed prior to the throat infection.

Chronic Inflammation and Ulceration of the Duodenum, with Resultant Reflexes.—Dr. J. M. Alten, of Kansas City, Mo., related in this paper clinical and pathological observations with regard to chronic inflammation and ulceration of the duodenum and resultant reflexes. This condition of the duodenum was very frequent, according to his studies, but had received very little attention from authors of textbooks. He thought he did not exaggerate when he stated that in his experience as many as five or six hundred cases in which there was a question between duodenal and gastric trouble had come to autopsy and a decision was rendered from gross and microscopical appearances. A very common cause of various reflex nervous symptoms, including such grave conditions as epilepsy, melancholia, and insanity, was chronic inflammation and ulceration of the duodenum. The most common origin of the latter was in typhoid fever, and it was seen in phthisis pulmonalis, chronic dysentery, acute irritation, etc. He had investigated thirty cases of diabetes mellitus, in all made a diagnosis of chronic inflammation of the duodenum, and confirmed it by autopsy in seven. Was the relation between the two direct, through interference with the digestive function in the duodenum, or was it indirect, through reflex interference with the nervous mechanism controlling sugar formation? Treatment included attention to gastric and rectal feeding. Epilepsy of this origin could be cured if treatment were begun before the second year of its existence.

Dr. Boardman Reed queried whether some of the cases might not have been due to disturbances of other portions of the gastro-intestinal tract and the nervous symptoms caused by toxæmia, instead of being reflex.

Dr. Alten did not believe that there could be absorption of toxins in the gastro-intestinal tract without a lesion of the mucous membrane. It was against reason.

Friday, June 4th—Morning Session.

Discussion on Gout.—The discussion on this subject was opened by Dr. Woods Hutchinson, of Buffalo, who spoke more particularly from the point of view of ancestral development. Attention was first called to the universality of gout, not only in man but also in the higher species of animals. As Sydenham had said, gout is the lord of disease and the disease of lords. It had been said that it did not exist much in our new country, but this was an erroneous impression, due to its manifesting itself usually in forms more or less different from that in the classical cases of England. Dr. Hutchinson mentioned some of the lithæmic forms of gout manifested in dyspepsia, neuralgia, hay asthma. Rheumatism—well, all we could say about it was that outside the acute inflammatory variety two-thirds of it was gout and the other third we knew nothing about. Gout also manifested itself in gynæcological affections, conditions of the larynx, degeneration of the arteries, leading to Bright's disease of the kidneys, etc. What was lithæmia? It must be something allied very closely to the normal processes of the body, or by its multitudinous manifestations it would soon exterminate the individual. It was a bad habit, a kind of alcoholic habit, so to speak, which the tissues had of falling into. It was a partial reversion to the avian or reptilian type in the metabolism of the cells. The same elements produced by the ultimate metabolism of our bodies caused in us gout, while in birds or reptiles it was in harmony with the normal health, and gout in them was the result of a further reversion. The same law could be traced even to plants. Treatment consisted in the employment of any means to keep the tissues up to the highest possible degree of metabolism and vigor. Exercise, more exercise, more exercise! "Live on a shilling a day and earn it!"

The Gastro-Intestinal and Hepatic Relations and Manifestations of Gout.—Dr. Charles Stockton, of Buffalo, read a paper on this subject. In his conclusions he stated that gout was a disease to which certain individuals were predisposed, and which depended for its development upon causes largely unknown. Laziness, full nitrogenous diet, and the use of fermented liquors predisposed to the disease. So-called lithæmia, as the term was commonly applied, was not gout, but an auto-intoxication dependent upon gastro-intestinal derangement. The relation of the food to gout should be carefully ascertained in each case.

The Ocular Manifestations of Gout.—Dr. Charles A. Oliver, of Philadelphia, stated in his paper that all of the tissues of the eye might manifest gouty inflammatory conditions, and then considered these in detail, beginning with the lids and conjunctiva and proceeding to the retina and optic nerve. In gouty inflammation of the lids, more especially of the upper lid, there was swelling, tumefaction which came on quickly and passed away quickly. For this condition he would say use heat, heat, and more heat. He found several calcareous infarcts in the conjunctiva near the Meibomian glands of one man who refused to believe until these had been shown him that he was gouty. Soon afterward he had gouty joints. Gouty manifestations in the eyes often caused lancinating pains, quickly disappearing. They seldom caused ulceration. Inflammation in the back of the eyeball sometimes extended to the optic nerve itself, even as far as the chiasm.

The Relation of the Alloxur Bodies to Gout, or a Uric-Acid Diathesis, with Demonstration.—Dr. T. B. Futcher, of Baltimore, read a paper with this title. The conclusion from his experiments was that it was very doubtful whether there was any connection between the abundance of the Neisser granules in the blood and the alloxur bodies in the urine, and the blood of persons free from gout contained as many of the granules as that of gouty subjects.

The Relation of Uric Acid to Neurasthenia.—Dr. F. S. Pearce, of Philadelphia, arrived at nine conclusions of considerable length in this paper, which, so far as the relation of uric acid to neurasthenia was concerned, admitted such relation in some cases the full nature of which we did not understand. Diet had much to do with the matter, but underlying it all in many instances was a hereditary instability of the neurons, which could be controlled to an extent, but not eradicated. Dietary must be looked to in the correction of the faulty metabolism, also rest of body and mind, suitable diversion, massage, tonics, etc.

The Treatment of Gout. — Dr. H. C. Wood, of Philadelphia, spoke on the treatment and management of gout. He hardly knew what to say, for he was expected in fifteen minutes to epitomize the wisdom of the ages with regard to what was probably the most frequent of all conditions among what had been called the better class of the human race. He wished it clearly understood in the first place that all our scientific knowledge of gout at present amounted to little

more than a mass of trundling expectation upon which hereafter was to be built some true knowledge. To his way of thinking there were three great manifestations of the same thing which was universally allied to itself. They were rheumatoid arthritis, podagra or true gout, and articular rheumatism. We must not attempt to treat gout, but treat the individual who came before us. Take diet: it was well known that Sydenham believed that gout was made worse by red meats. Dr. Wood had seen gouty patients in whom a single piece of roast beef would precipitate a furious attack. On the other hand, he had seen many gouty people who could not get well unless they were put upon red-meat diet. There was no diet for the gouty, but there was a diet for the individual. Nevertheless, in the large majority of cases, sugars and starches had to be cut off. But in spare gouty subjects farinacous diet might be essential. Milk probably suited the largest number of gouty patients. In the matter of exercise, we must give the right measure to the individual patient. But patients who could take little when they first came under the physician's control could gradually be led up to the point of taking a great deal of exercise, and this was essential for prevention of further attacks. Dr. Wood also spoke of the best way to give salicylates that they might not disturb the stomach. The trouble arose usually from the fact that doctors gave the salicylate of sodium. Strontium salicylate was less disturbing. In some instances it agreed better with the patient when combined with digitalis and strychnine. Medicines, however, would not eradicate the diathesis.

The Cardio-Vascular and Renal Relations and Manifestations of Gout.—Dr. N. S. Davis, Jr., spoke upon this subject. The atheromatous changes which took place in the arterioles throughout the body, including those of the kidney, in the gouty subject were too well known, he said, to call for mention in detail. But some points in connection therewith had been referred to only in a broad way in the books, and were often overlooked. One of these was the gradual progress of the renal disease, the organ being hit in spots, with intermissions in the degenerative changes which were microscopical in size, until finally large areas were involved. In these cases the glomeruli and the tubules were attacked in a way at times to cause scarcely an appreciable symptomatology, whereas the same changes coming on suddenly, as in cases of a different etiology, caused striking clinical and urinary manifestations. The arterial changes in the nervous system led to various nervous disturbances by interference with the nutrition of nerve centres. Cerebral manifestations might arise from uræmia or from thrombosis of the cerebral arteries.

Dr. Tyson said that Heberden's nodosities did not mean gout, and also the fact that in the treatment or prevention of gout continuous use of alkaline waters was of great benefit, especially the foreign Vichy. Citrate of potassium was good.

Rheumatoid Arthritis.—Dr. David Riesman, of Philadelphia, read the paper. He preferred the term used by Virchow, arthritis deformans. Heberden's nodes were manifestations of rheumatoid arthritis rather than of gout. The theories which had been advanced in explanation of rheumatoid arthritis, or arthritis deformans, were: 1, that it was a form of chronic rheumatism; 2, that it was a mixture of inherited rheumatism and gout; 3, that it was of nervous origin; 4, that it was caused by a specific germ. The author thought the third was most in consonance with the symptomatology, etc. He related a case showing apparent benefit from strontium bromide. It had relieved the pain, and perhaps had eliminated the disease.

Discussion on Anæmia.—Dr. Alfred Stengel, of Philadelphia, was to have opened the discussion on anæmia, but in his absence his paper on "The Nature and Varieties of Anæmia" was read by Dr. A. E. Taylor, of Philadelphia. The studies of the blood by Virchow, Cohnheim, and others marked an advance in our knowledge of anæmia. One point emphasized by the author was that it would be an error to consider the blood from the standpoint of the corpuscular element alone. The tendency of the profession to regard the corpuscular element as the criterion from which to estimate anæmia needed correction. More attention should be given to the plasma. The author considered the several forms of anæmia or conditions in which anæmia was manifest—chlorosis, chorea, pernicious anæmia, etc. The term splenic disease ought not to be used—he knew of no disease which should be dignified by that title.

The Alterations in the Blood, and Methods of Determination.—Dr. A. E. Taylor then read his own paper on this subject. The most urgent need was an instrument to take the place of the hæmoglobinometer, as this instrument was very unreliable. The oxygen-carrying power of the blood was far in excess of the needs of the tissues, and the evil effects in anæmia were obviously not due to disturbed oxygenation. The author believed that the chemical study of the blood would henceforth prove far more important than the microscopical study.

The Salivary and Gastric Functions in Anæmia.—Drs. S. M. Hamill and D. L. Edsall, of Philadelphia, were the authors of this paper. Their study, however, seemed to have been limited chiefly to the ferment power of the saliva in anæmia. After speaking of the technique of collecting the saliva and the tests, they said they had applied those tests in several cases, including leukæmia, chlorosis, pernicious anæmia, etc. The conclusion reached was that anæmia *per se* did not give rise to noteworthy changes in the ferment activity of the saliva.

Optic Symptoms in Anæmia.—Dr. W. C. Posey, of Philadelphia, read a paper on the changes in the fundus of the eye in anæmia. While examination of the fundus often gave indications of anæmia, it did not always do so, especially in cases of anæmia of moderate degree. In chlorosis ocular manifestations were more frequent, the author thought, than was commonly supposed, for in nearly every case in which the hæmoglobin was markedly reduced he had found changes in the fundus. The most common change was a dull, lustreless, grayish appearance of the nerve. In pernicious anæmia clinicians had observed retinal hemorrhages, but they were not so uniformly present as some had supposed. As a rule they occurred in the advanced stage. In initial anæmia from loss of quantity of blood, there were seldom ocular changes unless some other factor than loss of blood existed.

A Further Report on Ischochymia (Dilatation of the Stomach).—Dr. Max Einhorn, of New York, referred in this paper to one which Senn had published in the Medical Record, 1891, reporting fifteen cases of stricture of the pylorus, and asserting that the condition was one for surgical treatment; also to a paper which Dr. Einhorn had read before the German Medical Society in New York, 1894, in which he used the name "ischochymia" to convey the idea of stagnation of food in the stomach as the principal symptom of the affection. In that paper he recorded four cases of stricture of the pylorus in which operation had been successfully performed, and several cases of malignant disease of the pylorus in which gastrostomy had proved of temporary benefit. More recently he had read a paper on ischochymia before the German Dispensary of New York, and to-day it was his intention to present a summary of work done to date. He divided the cases of ischochymia into two classes: 1, cases in

which an operation was indicated, whether the stricture were malignant or benign; 2, cases treated by palliative measures. The cases of benign stenosis of the pylorus submitted to operation numbered ten. In all of the cases operated upon the diagnosis was completely confirmed. Of the ten cases eight resulted in cure; two were advanced, and the shock of the operation was fatal. In the cases of malignant stricture of the pylorus, diagnosis based on the lactic-acid test and presence of tumor, the majority of the patients who survived operation gained in weight and were made more comfortable than by any other measure. The salient point in the diagnosis of ischochymia was the presence of food in the stomach from a meal taken the previous day. The question then arose whether we had to deal with weakness of the muscularis or with stenosis of the pylorus. The symptoms related to dilatation, thickening of the pylorus, arrested peristalsis, fermentation products. But the diagnosis ought, if possible, to be made before the occurrence of dilatation. When there was tumor and ischochymia had existed two years, one could make the diagnosis of benign stenosis. In his conclusions Dr. Einhorn pointed out that operative measures were usually indicated in both malignant and benign stenosis of the pylorus leading to ischochymia, the operation lying between excision, gastroenterostomy, and plastic procedures, according to the extent of the disease, etc.

Relation of Fat Necrosis and the Pancreas.—Dr. H. U. Williams, of Buffalo, was the author. The paper dealt more particularly with that form of fat necrosis associated with disease of the pancreas. This fat necrosis appeared in the fat on the surface of the pancreas and vicinity; similar nodules might be present in the fat of the peritoneum at points more remote, denominated disseminated or multiple fat necrosis. Peritonitis was not usually present. Dr. Williams had studied the pancreas in eighty dead subjects, and had found fat necrosis in only two. He had also examined the pancreas of one hundred hogs, and found fat necrosis in the interlobular fat in two. He had also met with what appeared to be the same change in the adipose tissue of the cat, but not near the pancreas. In some instances the fat nodules had been found sterile. The bacillus coli communis was oftenest present. The author had published in the *Boston Medical and Surgical Journal* results of his experiments with tying the nerve plexus of the pancreas and injuring the organ with a hook, causing fat necrosis.

Dr. Blaisbrook, of Washington, said he had been interested in this subject, and had examined the pancreas post mortem in one hundred cases for fat necrosis, and had found it in none. The only disease which he had found was carcinoma, and in one or two of these the gross appearance was that of fat necrosis, but the microscope showed cancer.

The Diagnosis of Abdominal Effusions and Growths.—Dr. James Tyson, of Philadelphia, related a recent clinical experience which seemed to him of sufficient interest to bring to the attention of the section. A few months ago there was a woman in his wards at the University Hospital with ascites, and some physical signs of that condition, notably succussion tremor. She had, however, very marked tympany in the flanks, so marked that it led his house physician strongly to doubt the presence of fluid; but his diagnosis of fluid was confirmed by drawing off several pints. The symptom had been found, but in less degree, in a number of cases of ascites in the hospital since then, and his colleague, Dr. Penrose, had met with it from time to time. Leube had mentioned that the large intestine, which went as far forward as the midaxillary line and was shut off by the peritoneum, might give tympany under such circumstances.

Drs. Bayliss, Rochester, and Allen stated that they had recently met with cases in which this tympany had caused some trouble in diagnosis.

The Treatment of Cancer by Zinc-Mercuric Cataphoresis.—Dr. C. B. Massey, of Philadelphia, described in this paper a use of metallic electrodes with high milliampère, up to one thousand or more, both electrodes being applied within the cancerous area in a manner presumed to cause diffusion of the metal into and throughout the cancerous tissue by cataphoresis. The metal thus diffused was supposed to be oxychloride of mercury, and it was believed to reach the cancerous or sarcomatous elements which had become disseminated into the surrounding healthy structures. His review of eight trial cases would show two cured, two apparently cured, two benefited, two failures permanently to arrest the disease.

Case of Primary Renal Tuberculosis.—Dr. J. D. Steele, of Philadelphia, read the history of a case of presumable primary tuberculosis of one kidney, and called attention to the doubt which had been expressed by some authorities as to the occurrence of primary tuberculosis of the kidney. First one kidney became diseased, and in about half of the cases the other became involved before death. The pelvis of the kidney usually escaped until late, and the ureter was seldom implicated. More frequently other organs were also the seat of tuberculosis.

Experience in the Treatment of Epilepsy According to the Method Suggested by Niemeyer.—Dr. Matthew Woods, of Philadelphia, read the paper. His reason for presenting it was that he had obtained better results from this treatment of epilepsy than from any other. The many varieties into which epilepsy had been divided was simply a multiplication of terms, and threw no light on the causation of the disease. He dwelt upon the surgical treatment—craniectomy, circumcision, etc.—because sometimes it was an important adjunct to drug treatment, and because he wished to show that too much importance had been attached to the brain as the seat of epilepsy and pressure on the brain as its cause. The seat of epilepsy could be anywhere, and any treatment not considering the starting-point must fail. One case he had cured by operating for epispadias, which had existed prior to the development of epileptic attacks. One woman burnt her hand, whereupon her epilepsy disappeared. The chief drug used by the author was bromide of potassium in gradually increasing doses taken in a large quantity of water—ten to sixty grains from one to four times a day, the treatment to be continued at least a year after cessation of the convulsions. In his summary he repeated that resort should be had occasionally to surgery, to relieve constriction of the prepuce, lacerated cervix, suspicious cicatrices; constipation should not be allowed to exist; digestion should be improved; a limited amount of animal food once a day; outdoor exercise; bromide of potassium in the manner stated.

Medicine as an Exact Science.—Dr. W. J. K. Kline, of Washington, read a paper which was a plea for exact science in the teaching and clinical application of medicine, so far as this science had been developed.

The Importance of the Habit of Prognosis in the Development of the Individual Physician.—Dr. L. F. Bishop presented a paper on this subject. He said it was the physician's duty to look out for new methods which tended to the better development of his work, as well as to keep informed and his mind trained by thought. Habits were the masters of lives and actions. These were as potent for good as for evil, and habits of mind and thought were as much habits as those of the physical nature. The habit of prognosis was important as not only looking to the condition of the pres-

ent, but what would happen if certain different lines were followed. It was well to form the habit of a careful prognosis, and by study and comparison this habit could be made more accurate. This prognosis should be faithfully promulgated to those who had a right to know it. The first step of prognosis was not the classifying of the disease, as might be indicated by the index of a book, but the placing of the case in a particular group of a particular variety of the disease. Then by thorough comparison and research the mathematical theory of chances and possibilities could be brought to bear and the conclusion reached. The insurance companies did not pretend to say that a certain man would live to a certain age, but by observation deduced the rule that the average age would be a certain one; so the habit of prognosis could deduce the conclusions that would in the main be accurate. The ideal mode of study of prognosis would be to compare different cases of the same disease treated by different methods with untreated cases, but such opportunities did not often occur; yet by careful study of the cases in hand and a summing up of the results, one could form conclusions that would aid much in the habit of prognosis.

Before adjourning, the section extended a vote of thanks to the chairman and the secretary of the section, Dr. Musser and Dr. Priestley.

(To be Continued.)

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, April 19, 1897.

JOSEPH E. JANVRIN, M.D., PRESIDENT, IN THE CHAIR.

The Treatment of Diphtheria in Private Practice; a Comparison of Antitoxin with Other Methods.—DR. JAMES J. CONCANNON read the first paper. During the pre-antitoxin period, treatment of diphtheria had been very variable, and it was so to-day among those who did not believe in antitoxin. Many doctors now advised parents to use antitoxin; others advised them to let it alone. Both sides were honest, but it was evident that many lives were being sacrificed during the solution of the question of the value of this treatment. The unsatisfactory results of other treatment were pointed out and were well known. The claims for antitoxin and the statistical basis therefor were also stated. Nearly all of the doctors who had contributed to the report of the American Pediatric Association favored the remedy. From certain of the statistics quoted it was shown that the mortality was only five per cent. when the serum was administered the first two days.

Dr. Concannon then analyzed thirty cases of diphtheria which he had (formerly) treated without antitoxin and twenty-three which he had treated with that remedy, and three others so treated seen with other physicians. In both instances he divided the cases into three classes, the mild, the moderately severe, and the severe. The mild, the moderately severe, and the severe cases were nearly equal in the two instances. The treatment in the thirty cases varied, and seemed to have been negative in effect. The internal administration of mercurials, pilocarpine, applications of nitric acid, nitrate of silver, etc., were harmful rather than beneficial. Insufflations produced little or no result. Papoid and so-called solvents had had no effect. Cleansing solutions had a place. Iron was good for the anæmia. In the twenty-six cases in which antitoxin was used the dose varied from fifteen hundred to twenty-five hundred or more units. There was no other treatment except tincture of iron in three cases, and irrigation with sea water in about half. As to results of the two methods, eight patients died under the old method, only three under the new. Excluding two cases already moribund, only one death could be placed on the antitoxin side. Under the old method there were nine laryngeal cases, five of which were intubated, and all five patients died before the tube was removed. Few or none of the laryngeal cases in the second class required intubation after use of antitoxin, which showed that antitoxin did away with the necessity of intubation. Severe cases under the old treatment required attention for weeks; under the new for days. Under the old treatment we never dared make a prognosis nor state what a remedy would accomplish; under the new we could state with much certainty that the membrane would disappear in forty-eight hours, the patient would be much improved in twenty-four hours, and would recover in a few days. The author had seen no ill effects from antitoxin. There had been successful immunization with the serum in several families exposed to diphtheria.

The author then considered charges against antitoxin. Grant that some sudden deaths had occurred; they had also occurred without the use of the serum. It was important to wait before making the injection for the air to rise from the serum drawn up into the syringe. The author was disposed to regard the injection of air as one explanation of accidents which might have occurred. Theoretically it might be supposed the antitoxin would be useless in cases of mixed infection, but in practice cases had shown improvement. The objection that the treatment lessened the number of the doctor's visits held. In his conclusions he asserted that antitoxin was a specific for diphtheria when used in time; that it was the only effective treatment known; that it was effectual as a prophylactic.

Results of Diphtheria Antitoxin in Forty-Four Cases.—DR. G. B. PHILHOWER, of Nutley, New Jersey, opened the discussion. In this country to-day there was no disease which so struck terror into a family when a member became affected as diphtheria. In view of its great fatality, he felt, as the author did, that every physician should be compelled to use antitoxin. During about ten years' practice before he became acquainted with the use of antitoxin, Dr. Philhower treated two hundred and eighteen cases of diphtheria, with sixty-six deaths, a mortality of thirty-one per cent. He felt that such a record was not one to be proud of; that it left too many vacant places in families; that he ought to save more lives. Besides, the treatment in vogue, the swabbing, the spray, etc., was disgusting to him. Therefore when a new remedy came out he was ever ready to inquire into it. Twenty-two months ago he began the use of antitoxin, and had since treated forty-four cases with only two deaths. The two deaths were in his first ten cases. One of the two patients died, two weeks after the treatment had cleared up the throat, of broncho-pneumonia. The average age was eight years, period of injection forty-eight hours, duration of sickness about four days. The only symptom on the increase under the treatment was laryngeal paralysis, but analysis of the cases showed that this was only apparent, due to patients recovering who formerly would have died. Laryngeal subjects used to choke to death, and subjects of nasal diphtheria died of infection. Now they were saved, but some of them had paralysis. It was not due to the antitoxin. He had seen a rash, but could not say that it was due to the antitoxin. He had discouraged other treatment except an initial dose of calomel, sunlight, and general hygiene. Of course it was possible that during the period he had used antitoxin he had happened to run across cases with less tendency to fatal issue than formerly, but there was no reason to think this, and the supposition was opposed by the

fact that other physicians in his village who had not used antitoxin had had the old death rate. The antitoxin which he had used was that prepared by the Newark board of health.

Dr. Adolph Rupp said he had used antitoxin only in one case, or rather he had advised it in a case in which the father was anxious to have it tried, for he had been a contributor to the fund early collected to supply an antitoxin in this city. Dr. Rupp saw the patient on the seventh day of the illness and the injection of antitoxin was made by the board of health. The pulse went up immediately after the injection; the fever rose, the membrane continued to form, the bacteria did not cease to flourish. He doubted whether the optimism of the first speakers was well based; certainly the literature, as Dr. Rupp had analyzed it, was not so favorable as it had been represented, not so favorable as the experience related to-night. The average mortality for diphtheria in Dr. Rupp's practice since 1881 had been less than fifteen per cent. A writer in Breslau had reported over eight hundred cases treated without antitoxin with a mortality of less than five per cent. The nature of the epidemic had much to do with the issue. There was much that was contradictory in antitoxin reports. The advocates of the method made too little of objections. It was easy to say that the patient died of heart failure. It explained as much as the assertion that the patient died for want of breath. What made the heart fail? Not diphtheria in the St. Louis child which received an injection simply for immunization; nor from the injection of air, for death did not occur until forty minutes after the treatment. During the last sixteen months the speaker had seen sixteen cases of diphtheria in three families, and none had proven fatal. Yet he did not claim to have any specific for diphtheria.

Dr. August Seibert had had favorable results with antitoxin treatment. Papers of the kind read this evening, giving excellent results from this treatment, had been published by the dozen. The testimony had been from men of such high standing that the results could no longer be questioned by any sane mind. It was simply the imperative duty of all physicians to use the serum early in every case of diphtheria. Dr. Seibert pointed out the apparent reluctance of one of the daily newspapers originally to give credit to Behring instead of Roux for the discovery of this treatment of diphtheria, and also mentioned the false prophecy of Dr. Winters with regard to the fate of this treatment and also that of washing out the stomach of infants, on which subject Dr. Seibert had written in 1888.

Dr. A. Lambert said it was true that the bacteria of diphtheria might be present in the throat without active diphtheria, but the board of health was compelled to take notice of such cases as possible sources of infection. He thought antitoxin was backed by far more facts, and by reasons based on such facts, than was true of the vast majority of our remedies. Of course its action was limited. It could not recuperate cells, but it would prevent their death by action of the toxins if it were given early enough. The amount of the toxin in the blood was unknown, but it had been found by experience that a less amount of antitoxin was required to counteract it in mild cases of diphtheria than in severe cases. Hence the variable dose, from one thousand units up to two thousand and more. To use it early and thoroughly should be the rule of practice.

Dr. Louis Fischer mentioned as among the chief reasons for failure with antitoxin the employment of a poor or bad quality; its use in cases already moribund; too small a quantity. He had known physicians to inject only fifteen hundred antitoxin units in malignant cases. It was not necessary to discard other treatment simply because antitoxin was used. Some people seemed to think that the new remedy should not only cure the child, but also take the place of food.

Urethroscopic Photographs.—Dr. Ferd. C. Valentine demonstrated on the screen the photographs, given him by Kollmann, of Leipzig. Drawings, afterward colored, had been made by different writers, especially by Oberlaender and Guyon, but they were not so reliable as photographs which were entirely free from the personal equation. Kollmann's excellent pictures had been taken by a camera devised by him for the purpose, and made a part of the Oberlaender urethroscope. Naturally they were in black and white. No retouching or beautifying pencil had spoiled their original strength or correctness. True, life tints were lacking.

Dr. Valentine then described about seven photographs representing various portions of the pendulous and anterior urethra in the normal and diseased state, the latter including strictures and papillomata. The dark mass at the bottom of all the photographs was the much foreshortened light carrier. One or other side of the urethra preponderated in the picture when the tube was directed somewhat to one side. Radiating folds were seen, the number and form of which depended upon the size of tube used. They represented the longitudinal folds of the urethra and projected from the periphery of the picture to the funnel. Striation of the urethra became more evident the larger the tube used, the larger tube flattening the longitudinal folds. The third picture showed the mouth of a Morgagni pouch. The fifth picture showed a similar pouch on the floor behind the glans, which was very unusual. The sixth picture showed stricture, Morgagni pouch, and Littré's glands opening into the urethra. The large craterlike Morgagni pouch was no doubt once the site of inflammatory process. From the gaping mouth it would be possible to remove secretion with Kollmann's spatula and examine for gonococci.

Dr. Carl Beck felt that members were under obligations to Dr. Valentine for this demonstration, which was the first one made in this country. He doubted whether the value of urethroscopy and urethroscopic photography had yet been grasped by the profession. He compared them to laryngoscopy and ophthalmoscopy.

Dr. Thomas Manley said that in no department of surgery had there been greater advance the past few years than in the surgery of the urinary tract and organs. He thought urethroscopy was of great aid in the treatment of disease of this tract, but that urethroscopic photography was likely to be chiefly of value in unusual cases.

Dr. Robert Newman presented some pictures in color of the urethra, which an artist had made under his direction some twenty-five years ago. The urethroscopic pictures had first been made by hand and afterward photographed and published.

New Battery Arrangements.—Dr. S. F. Brothers presented with Mr. Hailey some new battery arrangements, consisting of a water motor for charging a storage battery and connections for running a small dynamo by the storage battery. It could also be used for generating a faradic current.

Reports of Special Committees.—Several special committees made their reports. Dr. Stewart read that of the committee appointed to wait on the mayor and urge the appointment of a medical man to fill the vacancy in the board of commissioners of charities. The other members of this committee were the president and Dr. George T. Harrison. Dr. Harrison remarked after the report had been read that the mayor certainly could not now plead ignorance of the arguments of the other side, those opposed to the action of the commissioners of charities in their sweeping removal of physi-

cians to the city hospitals and placing such appointments in the hands of a narrow medical clique. The committee had presented the matter before the mayor verbally and in writing, and showed that the opposition to a medical man in the commission came only from the few who would continue the control of the hospital appointments by the colleges. The greater part of the work of the charity commissioners could be understood and discharged only by men having a medical education, and as long as no physician was on the commission its members had to depend for their information upon the statements of the doctors in the clique referred to. The medical profession at large had no representation. The so-called fourth division of Bellevue represented itself alone, and was the closest corporation imaginable. The new method of appointment to hospital positions, placing the appointments in the hands of the colleges, was uncalled for, since the colleges already had far more facilities for hospital instruction than they made use of, and many of the city hospitals now placed under their control were inaccessible for teaching purposes.

The report was accepted.

Presidency of the Board of Health, etc.—The special committee, composed of Drs. McLeod, Manley, and J. Blake White, to report on matters relating to the board of health, reported in opposition to the compulsory reporting of cases of tuberculosis, but in favor of abrogating that provision in the charter which prohibits the appointment of a physician as president of the board of health. The latter part of the report was adopted. The part relating to tuberculosis led to a vote, which by some of those voting meant its rejection and by others its adoption as a whole. The committee was continued, and no doubt the sense of the association on this question will be made clear at another meeting.

The Dispensary Abuse.—Dr. McGauran read the report of the committee on this subject. It had acted with the Charity Organization Society in presenting a bill at Albany, which bill was well replaced by the following:

"Section 1. By this act a dispensary is defined to be any institution, agency or place, society or association, whose actual or alleged purpose it is to furnish either gratuitously, or at a merely nominal price, to indigent, needy, or other persons not resident therein, medical or surgical relief, advice or treatment, medicine or orthopædic or other like appliances.

"Sec. 2. On or after the first day of October, 1897, it shall not be lawful for any one to establish, conduct, or manage at any place in this State, a dispensary not duly incorporated as such under the laws of this State, or not connected with another incorporation and licensed by the State board of charities.

"Sec. 3. In no case shall a dispensary be established, carried on, or conducted in any place in this State commonly known as a 'drug store,' nor in any place or building in the State defined by law or by an ordinance of a board of health as a 'tenement house.'

"Sec. 4. It shall not be lawful for any person or persons to display the word 'dispensary,' or to cause the same to be published in any form or in any manner in order to attract any indigent, needy, or other person to any dispensary not duly incorporated or licensed as provided in Section 2 of this act.

"Sec. 5. Any person who shall by means of any wilful false representations on his or her part, obtain at any dispensary medical or surgical relief, advice, or treatment, medicines or orthopædic or other appliances, or any person who shall wilfully violate any of the provisions of this act shall be guilty of a misdemeanor, and upon conviction shall be required to pay a fine of not less than fifty nor more than two hundred and fifty dollars.

"Sec. 6. The State board of charities is hereby empowered to make rules and regulations and to alter and amend the same when, in its opinion, necessary, in accordance with which indigent, needy, or other persons shall be given medical or surgical relief, advice or treatment, medicines and orthopædic or other like appliances by such duly incorporated or licensed dispensaries, and the said board is hereby empowered, a chance for a hearing having been given, to annul the incorporation, or suspend the operations, or to revoke the license of any dispensary for wilful neglect or failure on the part of its managers, trustees, officers, or employees to comply with the rules and regulations so established by said board; but nothing in this act contained shall be construed to mean that said board shall have power to determine the particular school of medicine under which the dispensary shall be conducted.

"Sec. 7. All acts or parts of acts inconsistent with the provisions of this act are hereby repealed.

"Sec. 8. This act shall take effect on the first of October, 1897."

Dr. McGauran said this bill had passed the senate and assembly, and only required the signature of the governor to become law. He made a motion, which was carried, urging the governor to sign the bill.

On motion the association appropriated $100 to defray part of the expenses for securing this legislation.

Representation in the State Board of Medical Examiners Demanded.—Dr. Robert Newman offered the following, which was adopted: "*Resolved*, That this association, representing over one thousand physicians in the county of New York, considers it fair that the New York State Medical Association should have a representative on the medical examining board, and, therefore, is in favor of the bill introduced into the legislature for such purpose."

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNÆCOLOGY.

Stated Meeting, April 22, 1897.

S. Marx, M.D., Chairman.

Specimens of Appendicitis, of Hydrosalpinx, of Extra-Uterine Pregnancy.—Dr. Andrew F. Currier presented a vermiform appendix removed with successful result early in the disease from a boy sixteen years old. The operation verified the diagnosis of appendicitis with abscess. He also presented the left tube and ovary removed for hydrosalpinx from a woman who showed some symptoms the seventh day after the operation, and it was found that there were stitch-hole abscesses, a rare complication in modern antiseptic surgery. The third specimen was one of extra-uterine pregnancy from a woman who had had some ovarian symptoms for a year, with pain. The day before Dr. Currier saw her she had pain, nausea, and vomiting, and next morning collapsed on the way to the bathroom, and was picked up from the floor. She rallied, and when Dr. Currier saw her he made examination under chloroform, felt a tumor on the right side, operated, found blood in the peritoneal cavity, and hemorrhage going on from the site of a ruptured right tubal pregnancy. The patient did perfectly well. The fourth specimen was also one of extra-uterine pregnancy from a woman who gave a history of former gonorrhœa, contracted from her husband, and more recently another attack with symptoms of peritonitis. The night before he was called she had an attack of hemorrhage during coitus, very severe pain, and next morning when he saw her she was very weak, with a pulse of 150. He operated and found ruptured tubal

pregnancy with fœtus. Four days later he was called by her physician, and on arriving she was dead. The cause of death was probably heart failure and not hemorrhage, for her husband said she had before had attacks of dyspnœa. An autopsy was rejected.

Dr. Currier said that in both of these cases it was the right tube which was the seat of the extra-uterine pregnancy, and this was true of most of his other cases. The last-named case was one of bicornate uterus; he could not say whether that fact had any etiological bearing.

Tumors of the Uterus in Maiden Women.—Dr. Robert A. Murray presented two specimens of papillomatous tumors of the uterus, and made them the basis of some remarks. The first specimen was from a maiden woman, aged fifty-nine, who while suffering from an attack of grippe employed a nurse. The nurse learned that she had a purulent and hemorrhagic discharge from the vagina, and it was then that Dr. Murray was called. He found a polypoid tumor projecting out of the vagina and attached to the cervix, twisted it off, and curetted the uterus with a blunt curette and irrigated. The discharge ceased. The second specimen was similar, and was from the widow of a physician, sixty-two years of age, who was suffering from grippe and pneumonia, and was found to have a foul, purulent, and bloody discharge from the vagina. Examination revealed a polypus projecting from the cervix. He twisted it off, washed out the uterus, curetted, and the patient was now well.

Dr. Murray dwelt upon the necessity for respecting the sense of delicacy in women, especially girls and maiden ladies, who were apt to suffer for months or years with pelvic troubles through fear of exposure should they consult a physician. Personally, he had never been refused permission to make such an examination as was necessary to lead to a correct diagnosis and to carry out appropriate treatment, but he first proposed a rectal examination and later a vaginal one, if the former proved unsatisfactory. The hymen was spared whenever it was possible to do so. The use of a speculum was seldom necessary to determine the cause of flooding. An unmarried woman might have fibroid, polypus, endometritis, displacement, ovarian trouble, but she rarely had cancer at the menopause.

The chairman, Dr. Marx, supposed there were members who disagreed with Dr. Murray regarding rectal examination, the use of the speculum, the use of dilators. These questions were open for discussion.

Dr. H. J. Boldt said that when it was necessary to enlarge the cervical canal to remove the tumor he would not resort to dilators; it was safer and gave more room to make a bilateral incision into the cervix. The cut would heal by primary union after introduction of a suture.

Dr. A. P. Dudley objected to speaking of women menstruating after the menopause. It was then hemorrhage, and any hemorrhage after the menopause was suspicious and should lead to an investigation. A rectal examination would nearly always have to be followed by a vaginal examination, and he preferred to begin with the latter. He had examined many girls with the little finger and made the correct diagnosis. If in operating it was necessary to enlarge the cervix, he would dilate with laminaria tents in preference to making incisions, as recommended by Dr. Boldt. In girls and unmarried women it was more difficult to sew up the incision than to remove the polyp. In fibroids at the fundus the hymen could not be spared, and incision of the cervix enabled one to make a quicker operation than by dilatation.

Primary Cancer of the Fallopian Tube.—Dr. H. J. Boldt presented a tube and ovary which he had removed that day per vaginam after having ruptured the tumor during examination. Only blood was found, and the appearance of the ruptured tube on gross examination was that of tubal gestation, but the pathologist, who had made an incomplete examination of the specimen, thought it was cancer of the tube, in all probability primary. It would be reported upon further at a future meeting.

Cancer of the Cervix with Isolated Involvement of the Fundus.—Dr. Boldt presented a second specimen consisting of cancer of the cervix with isolated cancerous spot in the body of the uterus. It was another illustration of the point made by him at the meeting of the American Gynecological Society in Brooklyn some years ago, that we should not be satisfied with supravaginal amputation of the cervix for carcinoma apparently limited to the cervix, for frequently there co-existed without our knowledge cancer of the uterus without tumefaction and seemingly independent of the disease in the cervix. Dr. John Byrne deserved great credit for his pioneer work with the galvano-cautery, but Dr. Boldt thought the advantage over the knife was not because of the cautery being electric, and personally he preferred the use of the Paquelin cautery.

Specimen from Early Abortion.—Dr. Dudley presented the products of an early criminal abortion, apparently a double uterine pregnancy, two sacs. The woman visited him bleeding, after having made three visits to an abortionist. He informed her husband of the circumstances and then removed the loose products of conception from the uterus. The patient recovered.

Result of Hysterorrhaphy.—Dr. Dudley presented the uterus and appendages removed for pyosalpinx on one side and ovarian tumor on the other in a colored woman upon whom he had operated four years ago for retroverted uterus, suturing the uterus to the abdominal wall anteriorly. This was an operation which he had some time ago said he would never repeat, and the present case gave good reason for that resolution. On opening the abdomen at the recent operation he found that the uterus was not close to the abdominal wall, but was suspended from it by a pedicle an inch and a half long. To the posterior wall of the uterus the small intestine was adherent and knotted into a mass to the extent of a foot. In front the uterus was bound to the bladder and it was this pathological condition which had given rise to her most severe symptoms. Separation of the adhesions required nearly an hour. Subsequent to the operation symptoms of intestinal obstruction developed, and Dr. Dudley wished to reopen the abdomen, to which proposition the consultant did not agree. Autopsy showed twisting of the gut at the site of the former adhesions. He repeated that hysterorrhaphy placed the uterus in an unnatural position, and he would never resort to it again.

The Use of the Curette in Puerperal and Chronic Endometritis.—Dr. Reuben Peterson, of Grand Rapids, Mich., read the paper. In the introductory he said he did not object to the general practitioner using the uterine curette, but he should do it only with clear ideas of what he wished to accomplish, and after having had that amount of experience with surgical work which had developed the habit of securing and maintaining strict asepsis. He had seen serious results from curetting practised by careless or inexperienced persons, and believed that such instances were too common.

Speaking of cases of abortion before the fourth month, the treatment applied by the author, he said, consisted in thorough emptying of the uterus, a sharp curette being used, since the dull instrument was inefficient; then irrigation with sterilized water. He did not use antiseptic fluids, because he regarded the danger of some passing through the Fallopian tubes as

real. The puerperal uterus should never, in his opinion, be packed tightly with gauze. Nor did he believe in using the fingernail instead of the curette, as it was liable to convey infection. Perforation of the uterus had often occurred, and to avoid this accident the operator should first have made careful measurements of the organ.

Concerning the puerperal septic uterus, the author quoted Bumm, and divided the cases into two classes, those in which the infection was local and shut off by a granulation zone, and those in which it was general. In cases of sapræmia, and, indeed, in all septic puerperal cases, he curetted with the dull curette, avoiding the sharp curette because of the danger of opening up new channels of infection. Retained membranes should be removed; then should follow irrigation with sterilized water. In the second variety of cases local symptoms were subordinate to general symptoms, and the protecting granulation zone could hardly be said to exist; the lochia was not so foul as in the sapræmic cases. Little hope was offered by any treatment.

The curette was useful in all forms of non-puerperal chronic endometritis. The sharp instrument was required; the dull one had been inefficient in his hands even in catarrhal non-septic cases. Gonorrhœal cases required caustics after curettage, although some had argued that they were contraindicated as interfering with drainage. There should be free exit for fluid; gauze should not be used in a manner to interfere with this, if it were used at all.

Dr. H. T. Hanks opened the discussion. In speaking of the manner of packing, it is not wise, he said, to pack tightly. Certainly the cervical canal will not bear tight packing, and the uterus does not require it excepting after the removal of an intra-uterine tumor, and generally not then. But he believed that a good iodoform gauze packing can remain, and is beneficial if it remains two or even three days in cases of endometritis of some weeks' or months' standing. The only caution which he would give to friends and students is that after the thorough curettage the gauze should be loosely packed in all parts of the cavity, and not packed at all at the internal os; only the small strip of gauze, not wider than one inch, should simply be left straight in the cervical canal. Such a packing never causes uterine colic. The uterus never rebels. But when the cervical canal at the internal os is packed tightly, there is less opportunity for drainage, and there is an exciting cause for uterine colic within a few hours. One does have pain and fever, and many times the surgeon believes that he has a case of iodoform poisoning or of septic inflammation, when nature is only trying to throw off the offending body at the internal os.

Another matter of great importance is the kind of medicament with which to saturate the gauze. He believed that good iodoform medicated gauze in the uterine cavity is better than sterilized plain gauze. He further believed that the iodoform in the gauze has a decidedly beneficial effect in chronic endometritis and metritis, over and above the well-known fact of its keeping the gauze sweet while in use, for two or three days.

He substituted to-day for iodoform, "nosophen" and its component, "eudoxin." These are just as good medicaments, and they are far less offensive than iodoform. He had used constantly for more than a year, in all his private practice, eudoxin or nosophen gauze. In about one-half of his cases of uterine packing in the Woman's Hospital, he had used this gauze with most satisfactory results. He knew the effect of the nosophen and eudoxin powders on the raw and abraded surfaces, like those following burns, etc., and he therefore believed it has a direct special effect on congested abraded surfaces in a cavity, other than the mechanical effect.

Nosophen contains over fifty per cent. of iodine, and has no odor, and therefore a one-per-cent. or a two-per-cent. mixture in glycerin certainly ought to be a satisfactory medicament for saturating gauze. And in the author's hands it has been altogether most satisfactory.

Dr. Currier mentioned a case to emphasize the fact that it was best to leave the operation of uterine curettage to those in whose specialty it belonged. He thought the author had not given sufficient credit to gauze for drainage. The precaution should be taken in introducing it pointed out by Dr. Hanks. Regarding the kind of curette, many cases were perfectly amenable to the dull instrument. No doubt many had at times had bad results from employing methods which were too violent.

Dr. Dudley used the sharp curette in puerperal cases before the third month, the dull one later. The best instrument was the irrigating curette, which rendered the parts antiseptic the moment it was used. The forceps sometimes removed material better than the curette. In endometritis he painted the interior of the uterus after curettage with pure or ninety-five per-cent. carbolic acid. For packing he used dry iodoform gauze. Glycerin iodoform gauze favored absorption of the iodoform and poisoning. In chronic endometritis he curetted the fundus with the dull instrument, the cervix with the sharp one. In gonorrhœal endometritis he used nitrate of silver, forty grains to the ounce. It was the best germicide for the gonococcus.

Dr. Boldt always washed out the uterus before curetting, and if it were not a septic case no harm would be likely to result in the event of accidental perforation. He had no use for the dull curette except just after delivery, when some of the secundines had been retained, but in most of such cases the fingers would do better. One could not tell how much force to employ with the dull curette. Gauze did not act as a drain, whether packed tightly or loosely. It had only two purposes: to cause contraction of a large uterus, to secure hæmostasis. Dr. Dudley had said that carbolic acid, when used pure, was not absorbed because it formed an albuminate. It was because it formed an albuminate, which destroyed its penetrating germicidal power, that Dr. Boldt did not employ it pure, but diluted one-half with glycerin.

Dr. R. A. Murray mentioned a case showing that the dull curette (used by another physician) had no power to stop the septic symptoms, whereas the sharp curette which he employed when called to the case set the patient at once on the road to recovery. He had no use for the dull instrument. He introduced no gauze, made no applications unless of iodine, which seemed to contract the uterus somewhat. Packing was indicated only for bringing about contraction.

Dr. Egbert H. Grandin thought the paper had been a protest against the injudicious use of the curette and in favor of the rational use of gauze. In so far he agreed with the author. He had tried all methods of treatment in non-septic endometritis and had come to curettage as the only rational one. But it must be used with discretion. The only place for the dull curette was for removal of secundines which were not infected, but here the fingers would do better. He resorted to the sharp curette also in putrid infection of the puerperal state. In gonorrhœal endometritis he used the nitrate of silver, one hundred and twenty grains to the ounce. If he introduced gauze at all, it was only plain gauze and for twenty-four hours. He had tried all kinds of applications, carbolic acid, nitric acid, etc., and had given them up. He now mopped out the uterus with alcohol; it might be of some value.

SECTION ON GENERAL MEDICINE.

Stated Meeting, April 20, 1897.

LOUIS F. BISHOP, M.D., CHAIRMAN.

The Nomenclature and Mode of Production of Auscultatory Signs in Pulmonary Diseases.—DR. EGBERT LE FEVRE read the paper. All teachers of physical signs relating to the chest must have noted the difficulty of conveying to students the meaning of certain terms used in books on physical diagnosis, for under the same terms different writers had described different conditions or sounds. In confirmation of this statement the author quoted freely from several writers, including Musser, Vierord, Gibson and Russell, Powell, Page, Loomis, Flint, Da Costa. These quotations would give a fair conception of the mode of production of the physical signs according to the views of the several authors. It was evident that there was an attempt to adapt the definition to the several theories of production, and *vice versa*. The three prevailing theories of the production of the auscultatory sounds were: 1, That the vesicular murmur was nothing more than the sound made by the glottis modified by transmission downward; 2, that it was produced entirely in the alveoli; 3, that there was a combination of the two sounds from the glottis and from the alveoli.

The reader regarded it as absolutely necessary to a correct interpretation of the physical signs to have a true conception of the facts which went to make up vesicular or respiratory murmur. He offered the following as a working hypothesis: There was no doubt that the sounds due to vibrations in the larynx were conducted down the bronchial tubes, but this was not the only basis of the respiratory murmur. At each inspiration the tidal air, equal to about thirty cubic inches, was carried through the bronchi and alveoli, and all the air in the pulmonary tract was set in motion. The sound arising from the air passing through the glottis was transmitted almost unchanged to the division of the trachea. At this point the column of air was broken up by impinging on the bronchi, then another sound was produced, less intense than the first named; at the next division there arose in a similar manner another vibration and sound, and so on down to the finest bronchioles. The farther the column of air proceeded in distance and in subdivisions, the less intense the succeeding sounds became. The first sound might be denominated tracheal, the next one a combination with this of the first bronchial, and so on. In certain physical states the upper tracheal and bronchial elements were more predominant than in others. In view of the fine divisions of the air column when it reached the terminal bronchi and alveoli, and its slow movement, it could be assumed that little sound was added there. The intensity of the sounds conveyed to the ear would depend upon their original character modified by the structures through which they were conducted—the resiliency of the lung tissue, etc. The difference in tensity of the lung tissue in inspiration and expiration would go far to account for the greater intensity and duration of the respiratory murmur on inspiration.

There was much difference of opinion regarding the production of crepitant râles. Some writers claimed that they were due to separation of the adherent walls of the alveoli when the air entered the lungs. Others held that they arose in the pleura. Regarding the former view, Dr. Le Fevre replied that the alveoli were rounded, did not become completely collapsed, so that there could not be a separation of their walls in the sense spoken of. He was of opinion that the sound was due in part at least to the air passing fluid exudate on entering the air vesicles. Similar sounds could be made in the pleura.

Ought we to do away with such terms as rude respiration, broncho-vesicular respiration, etc., and limit ourselves to fixed terms indicating the characters of sound—intensity, duration, and quality? Ought pitch to be left out of consideration, as had been done in recent text-books?

DR. W. H. KATZENBACH thought the author's hypothesis regarding the normal respiratory murmur was an ingenious one, and furnished a good working basis. He had himself been dissatisfied with the term vesicular breathing, for he had not been convinced that the normal respiratory murmur was produced in the air cells. He had been rather disappointed that the author had not referred to some of the observations of Dr. Leaming on the production of the respiratory murmur. Dr. Leaming had held that there was no more than molecular motion in the air cells, which was noiseless, and that the respiratory murmur was due to friction of the air passing through the bronchial tubes, this sound modifying the tubular sound coming from the glottis and trachea. When the density of the lung was changed, the character of the sound became modified. In his early study Dr. Katzenbach had been associated with Dr. Flint, who laid stress on four elements in sound—namely, duration, intensity, pitch, and quality. Regarding the origin of the crepitant râle, he believed the majority of those with whom he had conversed rejected the view that it was produced in the air cells themselves. Whether it was produced in the terminal bronchioles, as explained by Dr. Le Fevre, he was still a little in doubt. He had for a number of years considered it a crepitant râle from the pleura.

DR. CHARLES E. QUIMBY said the views of the production of the respiratory murmur and on the use of terms, as expressed in the paper, were exactly those which he had been teaching students for seven years. Five years ago he had presented half a dozen patients before this section, and had those examining them mark on a piece of paper what they heard at different localities over the chest, and in no instance did any two doctors use the same term to express what they heard. Four years ago he published a paper in the MEDICAL RECORD, which he had read before the Academy of Medicine, expressing the views, though in more technical terms, to which we had listened to-night, and it gave him great pleasure to know that he was not alone. As stated, seven years ago he had discarded the use of such terms as rude, harsh, or bronchial breathing, and had directed the attention of students to the intensity, pitch, duration, and quality of the sounds heard. When it came to known physical facts, no man's opinion counted for anything. The laws governing the production of sound had been demonstrated long before most of us were born. The only element in which a sound lost when once produced was intensity. The tracheal sound, for instance, retained precisely the quality with which it started when heard by the ear placed lower over the lung. There was no such thing as pure sound. The pitch was determined by the length of the tube set in vibration, being lower the longer the tube; hence the sounds from the larger bronchi were lower in pitch than those arising from the finer, shorter bronchi set in motion by the air impinging upon their walls, more especially upon the angle of separation. The intensity of any sound depended first upon the amplitude of the primary vibrations. When the angle of deflection in a dividing bronchus was great, the ingoing air suffered greater deflection, which caused greater vibration, greater intensity of sound. This would account for the breathing at the right apex being more bronchial than at the left, for the bronchus of the right apex made a

sharper turn on dividing. As the air proceeded downward it produced sounds which were higher in pitch but of less intensity. According to the case, the larger or the smaller tube sounds would predominate. He was convinced that in most normal cases the small tube sounds predominated, hence the sound was high-pitched. But high and low were only relative terms. If disease cut off the small tube sounds, we had left only the large tube sounds, or low-pitch bronchial breathing. Regarding greater intensity of sound on inspiration than on expiration, unquestionably tensity of the lung had to do with it, as pointed out by the author, but Dr. Quimby mentioned two other elements which he regarded as important. One of these was the direction of the air, being toward the ear on inspiration, away from it on expiration. The other was the fact that on expiration the vibrations were caused by the two columns of air impinging upon each other, whereas on inspiration they were caused by impact upon the firm bronchial bifurcation. On expiration it was the first period which caused most of the expiratory sound, occurring by relaxation, while the further outward movement of the air was slow and not strong enough to cause much vibration of the tubes. He agreed with Dr. Le Fevre with regard to the production of râles.

Dr. Knopf expressed pleasure on hearing the younger teachers of physical diagnosis making the attempt to get rid of too many terms and to use such as would be clear to all students. Regarding pitch, he thought a prolonged expiratory sound and change of pitch constituted a most important sign of beginning phthisis.

Dr. Le Fevre mentioned as proof of the fact that the respiratory sound was not due alone to the vibration of the air as it passed the vocal cords, modified as it entered the lungs, the experiment with inflation of the lung with the upper part of the trachea cut off; the respiratory sound was still produced. Regarding pitch, his ear was defective in appreciation of this element of sound, especially in physical diagnosis, being unable to separate it from the other elements, and it was a question how far the recent text-books were right in neglecting it and speaking only of intensity, duration, and quality of the sound. He was unable to say how many students were capable or incapable of recognizing the pitch of the respiratory sound.

Dr. Quimby said that in four years' teaching medical students he had found only two students whom he could not make appreciate the element of pitch in half an hour. Theodore Thomas was able to give the pitch of any sound immediately by ear.

Antiseptic Street Sprinkling.—The Colorado *Medical Journal* says that there are hundreds of tuberculous patients promenading the streets of Denver daily, and expectorating into the streets. If it were not for the constant sunshine, the healthy population would have no show against the invasion of these germs. The experience of several Denver physicians shows that tuberculosis is very much on the increase among the native population, and it is necessary to consider every practical means to stop its advance. The *Journal* suggests to the health department that corrosive sublimate be added to the water in the sprinkling carts of the city in sufficient quantities to be effective in destroying germs. "It is a simple matter to make this solution and nothing but good results could follow. If it be decided that corrosive sublimate could not be used in the metallic tanks, let formaldehyde be used. This procedure would make the dust of our streets less harmful and help to lessen the local spread of tuberculosis."

Correspondence.

OUR LONDON LETTER.

JUBILEE—THE PRINCE'S FUND—MEDICAL JOURNALS OF THE REIGN—ROYAL SOCIETY—COLLEGE OF SURGEONS—MUSICAL MURMURS—PARTURITION DURING PARAPLEGIA.

The great London festival to come off on Tuesday next, and inaccurately called the Jubilee, is absorbing all attention, and medical affairs occupy a back place even when doctors meet. *The Graphic* has published an illustrated programme of the royal procession and the proceeds of the sales are to be given to the Prince of Wales' hospital fund. The book is worthy of the artists of *The Graphic*, and will be treasured as a beautiful souvenir of the great pageant. The progress of medicine during the Queen's sixty years' reign is in itself a wonderful story. *The Lancet* was some fourteen years old when Her Majesty ascended the throne, and is still the leading medical journal. To-morrow's number will be the thirty-eight hundred and fifty-first. The next oldest is the *Medical Press and Circular*, No. 3,032 appearing last Wednesday. But this journal was for many years the *Dublin Medical Press* and afterward amalgamated with a much younger periodical, *The Circular*. It is still, however, the organ of the Irish school of medicine and may be regarded as the *Lancet* of Ireland. The *British Medical Journal* for this week will be No. 1,903, and has become the bulkiest of our three weeklies on account of the space occupied by the proceedings of the association and the freedom with which it prints official documents instead of abstracting or condensing them. All these journals have seen others started and after varying success discontinued. Most of them have done good service. A number still survive, with which you are acquainted through the practical nature of their contents.

On Wednesday Lord Lister as president received the guests of the Royal Society. It was the "ladies' night" and a brilliant exhibition. Telegraphy without wires and the *x*-rays were in the ascendant. A series of argon and helium tubes, displaying the words "Vivat Victoria Regina," arrested the visitors' attention on entering.

The Society of Members of the College of Surgeons have asked Lord Lister to allow himself to be put forward for election on the council of the college. There are at the moment five vacancies and eleven candidates, two of whom seek re-election.

A musical murmur is sure to arrest the attention of the auscultator, and the conditions under which these sounds are produced have not been fully worked out. They are often dismissed as phenomena of mitral regurgitation, but this is at best an imperfect explanation. Four cases of such murmurs were related to the Medico-Chirurgical Society by the president (Dr. Dickenson) at the last meeting, all of which were associated with aortic stenosis. They were all attributed during life to mitral regurgitation, but after death aortic obstruction was found in all. In three out of the four there was also mitral disease, but in one the valve was sound, while the aortic orifice was almost closed by recent vegetations. Dr. Dickenson suggested that the sound was due to the overdistention of the ventricle through the aortic obstruction, causing leakage at the mitral orifice from the abnormal pressure. A similar explanation was offered of the other cases, in which hypertrophy of the ventricle and aortic obstruction were associated with mitral insuf-

ficiency. The peculiar tone might be imparted to regurgitation in small volume but at high pressure.

Dr. N. Moore admitted Dr. Dickenson's ingenious explanation to be probably the correct one, though there might be others possible. The late Dr. Andrew taught that a systolic apex murmur heard at the angle of the scapula was due to mitral regurgitation, but if not heard behind it might be aortic. Information may sometimes be obtained by listening at the right suprascapular fossa as well as at the angle. A murmur, loud above but diminishing on passing downward and lost at the angle, is probably due to aortic stenosis. On the contrary, a murmur becoming clearer at the angle is probably mitral associated with aortic stenosis.

Dr. Amand Routh related to the Obstetrical Society an interesting case of parturition in the course of paraplegia below the level of the sixth dorsal vertebra, caused by an accident at nearly the seventh month of pregnancy. The patient was admitted to the surgical ward and remained there more than two months, was then transferred to a special ward, and labor came on two hundred and sixty-one days after the last menstruation, the first stage lasting ten hours, the second two and one-quarter hours. The placenta followed in five minutes. The only sensation during "a pain" was a "tight feeling" at the epigastrium. As the head passed the vulva the patient cried out, though she had no painful sensation; so it seemed only a reflex act. The "pains" were not so well defined as in normal cases, the intermissions being often incomplete—remittent rather than intermittent. After passing in review recorded cases, Dr. Routh thought we might conclude that (*a*) parturition is partly automatic and partly reflex, these acts corresponding mainly with the first and second stages; (*b*) direct communication with the brain is not essential to co-ordinate uterine action, though the brain seems to regulate the pains; (*c*) direct communication between the uterus and the lumbar enlargement of the cord is probably essential to the regular and co-ordinate contraction and retraction of the uterus in normal labor; (*d*) probably the uterus is able to expel its contents automatically as far as the relaxed part of the genital canal, even when deprived of spinal influence, but in the absence of reflexes the process of labor would be irregular and probably incomplete; (*e*) lactation does not depend on nervous influence merely, but is partly due to chemical changes in the blood, and these are in turn due to the metabolism of the pregnant uterus. Dr. Mott thought that the cause of the onset of labor was certainly bio-chemical, and suggested that the physiological stimulus is an increase of carbon dioxide in the placental circulation. In the conversation that followed it was evident that this point was of much interest, as was also the extent of reflex action in the case related.

PROTECTION OF THE DISPENSARY PATIENT.

To the Editor of the Medical Record.

Sir: I have just read with great regret your editorial comment upon a recent theft in a free dispensary. You have pointed out the fact of contributory negligence on the part of the patient, but you have failed to warn the philanthropists who devote their energies to dispensary benevolences of the possible source of danger to them. A jury would be likely to hold them responsible in such a case unless they could prove that they had exercised due care. This in turn might be taken advantage of by the occasional dishonest dispensary patient as an opportunity to levy blackmail. Bearing these facts in mind, I would humbly suggest that the dispensary managers, in compliance with the State law, supply a safe in the waiting-room, according to the custom in hotels and bathing-pavilions, and then post the usual notices warning people that the proprietors—or rather the philanthropists—will not consider themselves responsible for valuables not placed in the safe.

Louis C. Ager, M.D.

Brooklyn, N. Y.

THE FERROCYANIC TEST FOR ALBUMIN IN THE URINE.

To the Editor of the Medical Record.

Sir: A source of error in the use of this test, not heretofore mentioned, is due to iron in mineral water taken by the patient. In a case recently examined by the writer, a sample of urine, which gave but faint traces of albumin with Jolle's, Spiegler's, Tanret's, Roberts', Esbach's, and the heat and acid tests, yielded an abundant flocculent precipitate with the ferrocyanic test after standing half an hour. Sedimented in the centrifugal machine, the bulk percentage, at one thousand revolutions per minute for five minutes, was nearly seven, reduced to two and one-half at seventeen hundred revolutions for half an hour.

Differentiation from albumin can be made by observing the blue color of the precipitate when sedimented. The mineral water in question was that of Pueblo, Col.

Clifford Mitchell, M.D.

Chicago.

New Instruments.

THE HEMOSPAST.

By Veranus A. Moore, M.D.,

New York State Veterinary College, Cornell University, Ithaca, N. Y.

The extent to which the results obtained from blood examinations are being relied upon in making positive diagnoses renders improvement in the instruments for drawing even the little blood necessary for this purpose a matter worthy of attention. In addition to the examination of the blood by the physician for immediate assistance, it is being investigated more and more thoroughly in histological laboratories, and in determining the nature of many diseases the changes produced in the blood are receiving increased consideration. By any of the methods ordinarily used the procuring of fresh blood from the human subject for microscopic examination is somewhat clumsy and often annoying to the operator. Usually a surgical needle is employed, but with the anæmic and often nervous individual the sight of this simple implement, not to mention the making of the slight incision, causes much apprehension. This is especially true if it is necessary, as it sometimes is, to make two or more "stabs" before a sufficient flow of blood is obtained. In working with the smaller or experimental animals the task is less difficult, but even here the incision which is made with a scalpel, bistoury, or scissors, is unnecessarily long or deep. For the larger animals the spring fleam is very satisfactory, but it is not applicable for the smaller species or for the human subject.

The introduction of the hematocrit, for the determination of the number of red blood corpuscles, necessitates a slightly larger quantity of blood for each examination than was required for the counting-apparatus, and consequently aggravates the difficulties, by the present methods, of procuring the required amount. The desire for an instrument with which the incision could be made instantly, and the depth of the cut accurately regulated, led me to make several experiments in the construction of an apparatus possessed of these

qualities. The outcome was a spring needle lancet which works so admirably and which has so completely removed the difficulties attending the use of the surgical needle or bistoury that it seems worthy of a brief description.

The hemospast[1] consists of a metal tube (I have used brass) about five centimetres long and one centimetre in diameter, with the upper end closed and the lower one covered with a perforated screw cap which has a terminal regulator in the form of a smaller perforated cap. A narrow slot, three centimetres long, is cut in one side of the tube, beginning one-half centimetre from the lower end. In the upper part of the tube is a piece of coiled wire spring of sufficient strength to give the necessary force to a cylindrical plunger, carrying the needle, which is placed next to it in the lower part of the tube. The plunger rests against the cap. The incision is made with a triangular-pointed needle constructed with a shoulder, for convenience in handling, and which screws into the lower end of the plunger. From the side of the plunger projects a trigger which moves in the slot and with which the plunger is pushed up. When set the trigger is easily caught, by a slight twisting movement, into a notch near the upper end of the slot. By means of the regulator the length of the projecting part of the needle can easily be adjusted. When the spring is set the needle is hidden entirely from sight, so that if the instrument is exposed to view it does not suggest an implement of torture. In use it is convenient and easily handled. After the finger, or other part is cleansed and the incision is to be made, the instrument is pressed gently to the part, the trigger touched, and the incision of exactly the depth desired is instantly made. As soon as sprung, the hemospast can be dropped and the collection of the blood begun.

This instrument is equally efficient and much more convenient in procuring small quantities of blood from experimental and other animals than those which I have heretofore observed in the hands of others or employed myself. As it is made entirely of metal it can be sterilized in any of the germicides used in disinfecting surgical instruments, or by dry heat. If desired, it can be made larger and stronger, with needles of various sizes, and, if preferred, with a cutting edge of a millimetre or more in length. It is available, therefore, for workers in laboratories where normal human blood or that of healthy or diseased animals is being studied, as well as for the practising physician. Although simple in its design, there were a few mechanical difficulties encountered, for the overcoming of which I am indebted to Mr. W. C. Barnard for timely suggestions.

A NEW COMEDO EXTRACTOR.

By CHARLES W. ALLEN, M.D.,

NEW YORK.

THE instrument represented in the accompanying illustration has the advantage over others in use for the same purpose that it cannot become clogged; that the

lesion is kept in unobstructed view; that lateral pressure, massage, and gentle squeezing of the tissues can be carried out without injurious pressure, being possible by reason of a guard which prevents the arms of the instrument from wholly closing. In the handle a three-edged lance-shaped knife and sharp spoon are hidden. The former is sufficiently sharp for scarification as well as for opening pustules, deep nodes, etc., or for pricking the opening of the comedo follicle or incising its walls.

With the stylet closed the instrument can be carried in the pocket, and it offers the further advantage of a combination of all the instruments necessary in the local treatment of an ordinary case of acne vulgaris, or comedones.

It is made by Messrs. Tiemann & Co., 107 Park Row.

[1] "Hemospast" is the noun from the Greek combination of which the adjective form hemospastic (drawing or attracting blood) is already in use.

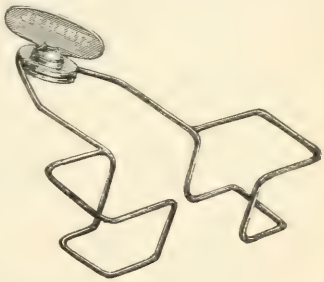
SELF-RETAINING ABDOMINAL RETRACTOR.

By JOHN N. BELL, M.D.,

DETROIT, MICH.,

GYNÆCOLOGIST TO HARPER HOSPITAL; LECTURER, ASSISTANT DEMONSTRATOR OF ANATOMY, DETROIT COLLEGE OF MEDICINE.

THE accompanying illustration represents a self-retaining abdominal retractor which I have recently devised. In removing pus-tubes, small fibromata, and multilocular cysts, with the patient in Trendelenburg's position, this instrument is especially useful; keeping, as it does, the field of operation widely exposed to view, the locating and ligating of bleeding points are greatly facilitated.



The shorter blades are entered through the abdominal incision and retraction of the walls made to any extent desired; the thumb-screw (which should point toward the pubes) is then set.

The instrument is at present in use at Harper Hospital, and gives perfect satisfaction.

Uses of Bananas.—It is hardly necessary to state that well-matured bananas that have not begun to decay are a very wholesome and nutritious food. No more than that the biggest apples or pears always are the best, are the biggest bananas the finest flavored; on the contrary, the larger they are the more mealy they taste. The cultivation of bananas, although it has in the last ten years assumed gigantic proportions, may still be said to be in its infancy. Almost every part of the plant can be used for some useful purpose; the stalk forms an excellent material for the manufacture of paper, or the fibre might be extracted; the peel of the fruit will make excellent indelible ink: the green fruit dried can be converted into wholesome flour. The fruit, when ripe, consists of seventy-four per cent. of water; of the remaining twenty-six parts, twenty are sugar and two gluten or flesh-forming food. Hence, like rice, though exceedingly nutritious, it requires the addition of some more nitrogenous material. Green bananas, boiled tender, if given to the hens, will make them lay more eggs than any other food. Dried bananas, or banana figs as they are called, are now in the market, and will undoubtedly soon be a great article of trade as soon as found by the schoolboy. They are sweet, wholesome, and nourishing.—*The Sanitarian.*

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 3, 1897:

	Cases.	Deaths
Tuberculosis	105	91
Typhoid fever	13	5
Scarlet fever	107	9
Cerebro-spinal meningitis	0	0
Measles	211	11
Diphtheria	249	25
Laryngeal diphtheria (croup)	12	7
Chicken-pox	12	0
Small-pox	4	0

Egg Albumen as a Medicine.—When the patient is hardly able to pay a doctor's bill, to say nothing of a drug bill, a cheap and handy substitute for fancy invalid foods is desirable. When fever is present and appetite is *nil*, and when we want an aseptic article of diet, Dr. Boynton says, the white of an egg raw serves both as food and medicine. The way to give it is to drain off the albumin from an opening about half an inch in diameter at the small end of the egg, the yelk remaining inside the shell; add a little salt to this and direct the patient to swallow it. Repeat every hour or two. In typhoid fever this mode of feeding materially helps us in carrying out an antiseptic and aseptic plan of treatment. Furthermore, the albumin to a certain extent may antidote the toxins of the disease. Patients may at first rebel at the idea of eating a "raw" egg, but the quickness with which it goes down without the yelk proves it to be less disagreeable than they supposed.—*Pacific Medical Journal.*

Tuberculosis.—The great white plague, as tuberculosis has been aptly termed, is the greatest disease scourge of the human race at the present day. According to Vaughan, one person in every sixty in this country is affected with the malady in some form. The world over, ten thousand human beings "cross the range" every twenty-four hours from this cause alone. The ravages of war and famine pale into insignificance when compared with the steady march of devastation of this fell enemy of mankind. No condition of life, no age is exempt. The infant in its cradle, the boy and girl at play, the young man at his desk, husband and wife, father and mother, the white-haired centenarian—all succumb to the invisible but invincible hordes.—*Denver Medical Times.*

Nephew of George Washington.—It is not generally known that a nephew of the first president of the United States was a member of the medical profession. Dr. Bailey Washington entered the United States navy as a surgeon in 1810. He died August 5, 1854. He was the surgeon of the *Enterprise* when she captured the *Boxer* during the war of 1812. He afterward acted with great efficiency on Lake Ontario under Commodore Chauncey, and was selected by him as fleet surgeon, although a junior officer in the service. He was afterward fleet surgeon under Commodores Rogers, Elliot, and Patterson in the Mediterranean, and closed his active sea service during the Mexican war. At the time of his death he was consulting and visiting surgeon of the navy yard and marine barracks in Washington.—*British Medical Journal.*

Hospital Car.—It is reported that a novelty in railway carriages will shortly be placed on the Belgian lines. This is a *wagon-hôpital*, fitted up, as its name implies, for invalids, and containing twenty-four beds upon wire springs, and various surgical and medical appliances. The new carriage will be utilized for the first time by the pilgrims to Lourdes next month. An unusual feature is a little chapel attached to the carriage, where by special permission from the Pope mass will be celebrated.—*The British Medical Journal.*

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service, during the week ended July 3, 1897:

		Cases.	Deaths.
Small-pox in United States.			
Memphis, Tenn.	June 13th to 27th	3	
Brooklyn, N. Y.	June 12th to 25th	1	
Cambridge, Mass.	June 12th to 26th	1	
Chicago, Ill.	May 1st to 31st	3	
Small-pox in Foreign.			
Bombay, India	May 25th to June 1st	2	1
Calcutta, India	May 8th to 15th	0	8
Gibraltar	June 6th to 13th	1	1
Hong-Kong, China	April 24th to May 22d	0	23
Madras, India	May 14th to 28th	0	1
Madrid, Spain	May 26th to June 8th	0	1
Nagasaki, Japan	May 29th to June 3d	7	
Odessa, Russia	June 5th to 12th	4	
Osaka and Hiogo, Japan	May 29th to June 5th	2	0
Matanzas, Cuba	June 5th to 12th	1	1
Sagua la Grande, Cuba	June 11th to 14th	45	
Trieste, Austria	May 22d to 29th	1	1
Havana, Cuba	June 17th to 24th	0	
Chihuahua, Mexico	June 22d	Reported.	
Crete, Italy	May 1st to 31st		2
London, England	June 6th to 12th	2	1
Glasgow, Scotland	June 5th to 12th	1	
Cholera.			
Bombay, India	May 25th to June 1st	0	15
Calcutta, India	May 8th to 15th	0	19

Santiago de Cuba	June 5th to 19th	0	1
Havana, Cuba	June 17th to 24th	1	2
Plague.			
Bombay, India	May 25th to June 1st		34

The Diagnosis of Uterine Cancer is not very difficult in the majority of cases, says Kessier in the *St. Petersburger medicinische Wochenschrift.* The text-books lead us to believe that it is always associated with cachexia; the suffering expression of the face, very frequent hemorrhages, fœtid discharges, etc., are not always present. But a serous discharge or bleeding between menstrual periods, and particularly a hemorrhage after the menopause, should make one very suspicious of malignant disease. He deprecates the practice of giving ergot or styptics in uterine hemorrhage when one suspects carcinoma, because while using these drugs the disease is progressing and valuable time is lost.

MORTALITY AND TREATMENT OF ACUTE INTUSSUSCEPTION—WITH TABLE OF TWO HUNDRED AND THIRTY-NINE CASES.[1]

BY C. L. GIBSON, M.D.,

NEW YORK,

ATTENDING SURGEON, ST. LUKE'S HOSPITAL.

IN the course of a systematic study of the recent literature of intestinal obstruction the writer's interest was particularly attracted, by the occurrence of several prominent features, to that variety due to invagination of the various segments of the intestinal tract. These were that intussusception, while presenting conditions allowing of easy and certain diagnosis much oftener than observed in other forms of obstruction, was nevertheless attended with no lesser mortality; again, that invagination of the intestines, unlike other varieties of obstruction, could in a certain proportion of cases be relieved by mechanical non-operative measures, and yet remained one of the most fatal.

A third point was the variance exhibited by the statistics collected by different authors, as exampled by Rydygier in 1895, giving a mortality of seventy-five per cent. in acute cases, and Wiggins in 1896, whose statistics in recent times and after the exclusion of certain conditions gave a mortality of twenty-two per cent. The conclusions reached by the latter writer in his most careful paper have been widely quoted and his painstaking work has received most favorable comment.

To the writer the low figure (twenty-two per cent. mortality) just quoted could not appeal, and it seemed to him that if he must answer his own query, why he was attempting to add to an already congested literature, he might find a reply in the effort to present the subject in a broader light. The essential reason, however, for writing this paper is to place on record a more extensive literature of the operative relief of acute intussusception than has ever been attempted before, the writer believes, in English or any other language. Rydygier in 1895 read a most exhaustive paper before the German Surgical Congress, based on his own large experience and the cases reported in the literature for the previous ten years (eighty-six cases), taking up the subject where Braun's statistics had paused in 1885. Braun's table contained sixty-six cases, going back to the earliest recorded in the seventeenth century. The literature of the subject then, as compiled by these German authors in 1895, comprised a total of one hundred and fifty-two cases treated by abdominal section, in which all cases—the chronic, lasting perhaps for years; those due to new growths, and therefore attended with special conditions; and the purely acute forms—were all included. But very slight observation convinced the writer of the necessity of a very definite separation of these forms for the purpose of studying the results of their treatment, and of the lack of a single exhaustive collection of cases of the acute form from which to attempt to derive fair conclusions.

The writer has collected two hundred and thirty-nine cases, divided into two classes: those occurring prior to 1888, eighty-nine cases, and those occurring since 1887, up to January 1, 1897, one hundred and fifty cases.

The division of time is somewhat arbitrary, representing in the second table the writer's convenience as to a part of his studies on the general subject of intestinal obstruction since 1887. These later years present conditions which make a comparative study of intestinal surgery most valuable. Antisepsis had already become quite well established and subsequently was reinforced by asepsis. Union of divided or non-adjacent portions of the intestine by mechanical aids had at the opening of this period been shown to be of great value, both in the improvement of results and in the encouragement of more frequent surgical interventions. The increased frequency of operations following familiarity with the possibilities of artificial methods of anastomosis led to eager efforts to improve the existing means, resulting in increased and better methods of suture and the temporary passing of the mechanical devices. In the latter part of this period, the best of these devices, the Murphy button, soon after its introduction in 1892, came to compete with and, to a great extent, divert attention from the improved methods of suture.

Then, again, many of the operators were no longer pioneers in the branch of abdominal surgery, relying on themselves to evolve measures of certain value, and the younger generation in its earlier efforts was now guided by the valuable teaching of the riper experience of its predecessors. The second table will therefore be used exclusively for the study of the conditions from which a fair estimate of the results obtained may be derived. Though the writer can claim an honest attempt to approach the subject by painstaking efforts of research, he has no illusions concerning its completeness, for he is aware of the existence of a number of observations in the literature of the English, French, and German languages that were either inaccessible or too incomplete to utilize. And, moreover, he has little doubt that he has overlooked some cases, for which no reason but carelessness can be advanced. The records of the first series prior to 1888 have not been the subject of the same care, as their smaller value on the whole seemed not to call for a like amount of labor. They have only exceptionally been derived from their original source, having been obtained almost entirely from the tables of Braun,[93] Barker,[62] Rydygier,[44] and Wiggins.[74] They are recorded for the sake of completeness and for their possible value to other investigators.

It has seemed wisest not to attempt a systematic and equal consideration of the various divisions of the subject of intussusception; but to concentrate the observations derived from the recorded cases chiefly upon a review of the causes and elements influencing the mortality attending abdominal section, and, guided by the results thus found, to attempt the outlining of a definite

[1] Read by title at the pædiatric section of the American Medical Association, June 3, 1897.

Three symptoms	7	2	2	1
All symptoms one case	1	1	1	
Total	29	45	11	6

* Compiled only from cases contained in Table II.

As regards diagnosis, little, therefore, need be said, as nothing new or important has been evolved from these researches. Attention is called to the table of symptoms (unfortunately quite incomplete); it will be seen that the presence of a bloody discharge from the rectum is the most constant symptom, and certainly, when present in a young child and accompanied by the sudden onset of abdominal symptoms, must be considered pathognomonic. Its absence, or in fact the absence of any one of the typical symptoms, does not imply that intussusception does not exist. The infrequency of fæcal vomiting is important to note, as some practitioners obstinately refuse to entertain a diagnosis of intestinal obstruction unless this symptom is present.

Notes on the finding of a tumor by abdominal palpation have intentionally been omitted, lest misleading deductions be drawn from them, the value of such observations depending largely on our knowledge of the observer's individual characteristics.

It may be stated, though, that in general palpation of the abdomen yields definite signs of greater value and more frequently than in other forms of acute intestinal obstruction. The lesser and more localized distention usually permits us to palpate the outlines of the intussusception, according to its classical description, as a sausage-shaped tumor. Absence of a clearly recognized tumor is not, however, a proof that intussusception does not exist.

Predisposing Causes.—The writer has no comment to make concerning the usual causes believed generally to be exciting factors in the development of intussusception. The greater frequency of this condition in male children leads him to speculate whether the straining due to a tight phimosis or to a contracted meatus may not have here the same etiological value as is ascribed to these conditions in favoring the development of hernia and prolapse of the rectum. He has unfortunately no notes relative to such conditions, and does not remember to have seen any allusions to the possible causal relationship.

Mortality.—The mortality as collected in the literature is by no means thought to represent that of actual practice; as a rule, the latter is usually considerably higher. It is believed though that the mortality given in these tables (fifty-three per cent.) will perhaps not show so great a discrepancy as in other conditions. Operations for intussusception are not so very frequent, and the great interest attached to them makes it probable that a greater number of the cases is put on record irrespective of the final results. The large number of cases of purely acute intussusception here recorded, occurring in modern times, should give a fairer estimate than previous publications based on a smaller number and dealing with cases operated on before the development of abdominal surgery. Moreover, these cases are all pure forms of intussusception, not due to the presence of or subject to the complications of the attending new growths.

The condition of acute intussusception is one of intestinal obstruction, and its mortality, like that of intestinal obstruction, is due essentially to the duration and cause of the obstruction. Also to be considered are, the site of the obstruction, the degree of the pathological changes of the intestine, the age (and sex). Another important factor having a particular bearing on the condition under consideration is the influence on the mortality of the variety of treatment employed, for it is believed that in no other form of intestinal obstruction is there a better opportunity for the exercise of good judgment as to what special procedure is indicated in any given case.

Results of operations alone are here based solely on Table II. Table I. and Table II. have been utilized in such observations as mortality according to age and sex, and site of obstruction.

TABLE IV.—Mortality and Operations Necessary According to Duration of Symptoms.*

Day.	Died.	Cured.	Total.	Mortality. Per Cent.	Reduction.	Artificial Anus.	Resection	Various.	Per Cent. Not reducible.
First	9	13	22	41	22	..	..	.	0
Second	11	18	28	39	24	3	1	.	14
Third	15	11	26	62	18	4	0	1	8
Fourth	14	4	18	77	6	3	5	..	57
Fifth	11	4	14	72	6	5	2	1	57
Sixth	2	1	3	66	2	..	..	.	0
Seventh	5	4	9	55	5	1	3	.	0
Eighth	1	4	5	.	.	2	1	.	
Tenth	3	0	3	.	.	2	1	.	
Eleventh	0	1	1	.	1	.	.	.	
Twelfth	1	1	2	.	1	1	.	.	
Fourteenth	1	.	1	.	1	.	.	.	
Third week	1	1	2	..	2	.	.	.	
Fourth week	2	1	3	..	1	..	1	1	
No date	8	6	14	..	8	1	4	1	
Total	79	77	149	53	99	22	24	4	33

* In these tables fractions of 0.6 or more are counted as a unit.

A glance at Table IV. shows that the total mortality for one hundred and forty-nine cases is fifty-three per cent. The first and second days show a mortality rate inferior to the general mortality, while the four succeeding days show a steadily increasing mortality, in each instance greater than the average. The end of the week shows a beginning decrease of the mortality, which it is to be hoped no one will undertake to explain by showing that better results follow delayed interference. After the first week we encounter the class of cases that merge from the acute into the subacute variety of symptoms.

The statistician working to prove that the mortality is in reverse ratio to the duration, would prefer that the mortality rate of the first and second days could be reversed; but on sober reflection the proportion can only appear natural, for these cases occurring on the first day are those in which the symptoms and their underlying condition may be properly called hyperacute. The writer found the same ratio of mortality some years ago when studying the fatality of appendicitis, when it appeared that the mortality rate of operation performed the first day was greater than that of operations performed on several days following. To the clinician of larger experience such conditions are well known and appreciated at their true value.

TABLE V.—Mortality According to Condition of the Intussusception.

	Number of Cases.	Died.	Mortality, Per Cent.
Reducible	97	58	59
Irreducible	31	16	51
Gangrenous	11	8	72
Irreducible or gangrenous	29	15	51
Total	149	79	53

As showing the acuteness of the process, it may be mentioned that in the nine fatal cases occurring on the first day, two died with symptoms of recurrence; one

died on the first day in collapse (eight months old); two died on the first day, autopsy showing general peritonitis; one died from intestinal paralysis; one on the first day with beginning sloughing of the gut and general peritonitis.

The mortality, according as the condition was found to be reducible or otherwise, is in direct proportion to the duration of symptoms. Of ninety-nine reducible cases thirty-eight died, mortality of thirty-eight per cent., while in the remaining fifty cases, in which reduction could not be performed, the mortality was eighty-two per cent., or more than double. As Table IV. shows how the proportion of non-reducible cases rose steadily after the first day, it requires no further demonstration that an early intervention is necessary for reduction and cure of the intussusception by virtue of its being reducible.

TABLE VI.—Mortality According to Procedure Employed.

	Number of Cases.	Died.	Mortality, Per Cent.
Reduction	99	38	38
Artificial anus	22	19	86.4
Resection	24	19	79.1
Various	4	3	

The mortality, according to procedures employed, is virtually only a check on the accuracy of the last-mentioned conditions, showing necessarily the same mortality for reduction—eighty-six per cent. for artificial anus, and seventy-nine per cent. for resection, or for both procedures eighty-two per cent. The significance of these figures will be further considered in another part of the paper. Under the heading "Various" are included three operations that were either abandoned or hopelessly incomplete, and one entero-anastomosis (cure).

TABLE VII.—Mortality According to Anatomatical Variety.

Variety.	Died.	Cured.	Mortality, Per Cent.
Enteric	20	11	64
Ileo-cæcal	45	22	33
Ileocolic	1	5	20
Colon	12	12	50

As regards the mortality according to the location, Table VII. shows that the ileo-colic variety heads the list with a mortality of seventy-two per cent., while the colon has the lowest—fifty per cent. These deductions, however, the writer believes to have only a relative value, as they are drawn from only one hundred and fifty cases out of two hundred and thirty-nine, and because doubts must in many instances arise as to the correctness of the classification, owing to the incomplete or loosely recorded details. The ileo-colic and enteric varieties have always been regarded as particularly

TABLE VIII.—Mortality According to Age.

Age.	Died.	Cured.	Mortality, Per Cent.
Three months or under	14	3	82
Six " "	31	17	64
Twelve " "	17	11	58
Five years or under	13	5	72
Ten " "	6	10	37
Fifteen " "	11	5	68
Adults	38	23	62

Under 1 year, 65 per cent. mortality
" 15 years, 61 " "
Adults, 62 " "

fatal, and it is rather remarkable that the latter does not show even a greater mortality. An explanation may perhaps be found in the considerable number of recent cases recorded, for in this class, when reduction cannot be effected, the improvement in the technique of reunion of the intestine after resection should prove of the greatest practical value, as in former times an artificial anus was the only resource, and this procedure, as we have seen, is necessarily attended by the highest mortality.

The mortality, according to the age, is of great importance. The observations are based on two hundred and eleven cases, their relative proportions being indicated in the accompanying table. The latter shows so remarkable a distribution of the mortality that doubts might well be raised against the value of such statistics, were they not derived from such a large number of cases. Dividing the age into three classes —infants (one year or under), children (fifteen years or under), and adults—we find only four per cent. difference between the highest and the lowest death rate. (It must be borne in mind that the mortality is represented by the sum total of the two tables and not by the one hundred and forty-nine cases since 1887). The writer believes that these figures have a value in calling attention to the fact that the mortality in intussusception is due not so much to the tender age of the majority of the patients but to the condition; also that this latter circumstance should prevent us from being sceptical of the possibility of improving our results, and lead us to discard the prevalent belief that we are dealing mainly with a class of patients whose age alone necessarily precludes a favorable result. While the tables certainly emphasize the terrible mortality in very early life, the improvement of eighteen per cent. in the second quarter of the first year is certainly gratifying and believed in all fairness to be sufficiently pronounced to justify such a conclusion.

TABLE IX.—Mortality According to Sex.

	Died.	Cured.	Mortality, Per Cent.
Male	53	24	67
Female	36	13	73

Mortality According to Sex.—For reasons which are in general sufficiently accepted and fairly constant, the female sex is supposed to show a larger proportion of recoveries after operations in general. The favoring elements generally ascribed as influencing the lesser female mortality would not seem to apply here, where the larger proportion of the cases was in children.

The mortality according to the method of relief employed will be more appropriately discussed under treatment.

It may be timely here to contrast the mortality of intussusception with that of intestinal obstruction in general. The writer has collected nearly six hundred cases of acute intestinal obstruction from causes other than intussusception, occurring within the same period of time (1888–1896) as the table of one hundred and forty-nine cases here recorded. They have been chosen with the same care relative to the exclusion of cases due to new growths, etc., and more rigidly as regards duration, none being included in which the time is not definitely stated, whereas, for the sake of completeness in these tables, a few cases, believed from their histories to be acute, have been included. In addition to the usual etiological causes of intra-abdominal obstruction, these cases include a large number of operations for gangrenous hernia, and yet the mortality in these cases, giving rise to a very large number of complicated and extensive operations, is only 42.01 per cent., while intussusception under the same conditions shows a mortality of fifty-three per cent. May not these figures, contrasted with each other, be taken to show that either we are dealing with a more serious

form of intestinal obstruction or that our methods of dealing with intussusception need improvement? The writer is strongly impressed with the reality of the latter possibility. The age alone of the subjects should not give so wide a variance Moreover, a reducible intussusception certainly appears to offer for speedy and simple operation conditions that do not exist in the majority of cases of intestinal obstruction. The intussusception, however, is not always reducible, hence the difference. Our figures show that the mortality of the reducible intussusception is inferior to that of other forms of obstruction, as thirty-eight is to forty-two. Therefore, if we aim to reduce the mortality of intussusception to the level of or below that of the general figures of intestinal obstruction, we must operate while reduction is possible. To accomplish the latter purpose we must operate at the earliest possible moment, and that means refraining from wasting precious time in attempts at reduction by inflation per rectum, except in a very limited class of cases, and such an attempt to be made only with the determination to resort to abdominal section immediately, if such inflation does not at once accomplish its purpose.

Treatment by Inflation of the Bowel by Enemata of Fluids (or Air).—It is probably not an exaggeration to say that if all cases of intussusception were treated at the onset, or say within forty-eight hours, by abdominal section, without any previous attempts at reduction, the mortality, while still considerable, would in all probability be very much less than the present figures. The writer is far from believing that mechanical distention should be altogether discarded, but would very much limit its application.

The vital argument against treatment by enemata of fluids or air is that such a procedure, should it not entirely succeed, delays operative measures. Also that it is uncertain, in that it may give rise to the deceptive impression that the invagination has been entirely reduced, while an unreduced intussusception, no matter how small, is still an obstruction of undiminished danger. A glance at the general tables will show how many instances occurred of deceptive successes following inflation, before resort was finally had to abdominal section. The records of such cases show that recognition of the success of the reduction must be very difficult from physical signs alone. To allow the patient to recover from the anæsthetic and to wait for symptoms is contrary to the indications of treatment of intestinal obstruction, which should consist in immediate and certain action.

Enemata are distinctly dangerous. The literature of intussusception in general is full of reports of cases of perforation or rupture of the intestines by the various agents used to reduce the invagination. Moreover these accidents are not invariably the result of what is unmistakably too great force or pressure. A striking instance of rupture from a hydrostatic pressure of only four and one-half feet is Case 126, Table II., reported by Harrington, that of a child five years old. The ileum was found perforated as the direct result of a fluid enema administered on the fifth day. Another typical example of perforation is reported by Mr. Fenwick,[82] where an intussusception in a six-months old child was apparently successfully reduced on the second day by an enema. Death occurring almost immediately afterward, the autopsy showed ulceration and perforation of the gut, which had not been reduced. This case shows plainly that the danger of perforation is not limited to interference in those cases that have lasted for a considerable period of time.

Another disadvantage of reduction by enemata is to be found in the tendency of the intussusception to recur; a number of such instances are to be found in the tables. Case 48, Table II., is an interesting example: the invagination was twice reduced and recurred twice before abdominal section was performed. While it may be rightly advanced that such recurrences are sometimes seen after abdominal section, they are undoubtedly rarer. Moreover, abdominal section permits of the employment of prophylactic measures against such recurrences, many surgeons having recently recognized the necessity of "anchoring" a newly reduced bowel, and in all probability such a procedure will become the rule when its necessity becomes more generally recognized.

Under what conditions then, if any, shall we make a trial of high injections before resorting to abdominal section? It seems to the writer that to attempt to reply to this question dogmatically would be a confession of inability to appreciate the complexity of the circumstances under which intussusception may be encountered. His feeling is that a single attempt (in a manner to be described elsewhere) may be made in the first twenty-four hours. If the condition is one of very great intensity of symptoms, it will perhaps be wisest to refrain from making such an attempt, for the reason that even on the first day reduction alone will not always be a sufficiently effective treatment of existing pathological conditions. A study of the analysis of the mortality of the first day (see above) will show that in at least three of the cases further procedures were called for. The case of beginning sloughing of the colon found at the autopsy is a sufficient proof of this contention.

In the second twenty-four hours, while a certain proportion of cases will in all probability yield to mechanical treatment, its usefulness becomes still more restricted, as exampled by the twenty-eight cases occurring on the second day (Table IV.), when in four instances other procedures than reduction were found necessary.

After the second day the writer believes that the possibility of relief is so small and the probability of doing harm so great that a preliminary trial of the enemata should be omitted, unless there are some specially good reasons for yielding to the temptation of resorting to them; for the tables show that after the third day, even after the abdomen was opened, a non-reducible condition was found in proportions varying from fifty-seven to eighty per cent.

A small percentage of cases, which may be called the subacute variety, may in the later days, say in the second week, offer conditions which might justify a preliminary trial of distention. These are the cases whose symptoms are a pretty accurate reflection of the lack of severity of the general or local condition, showing neither shock nor sepsis. Such cases, however, would from their excellent condition in all probability do well if subjected to the more radical and certain operation of abdominal section, if performed under favorable circumstances.

The pressure which can be used with safety has been shown to be limited. The same restriction applies to the amount. Mr. Pick[81] would limit the amount in a child under one year to a pint and a half, and the pressure to three feet. Parker cites a case in which an injection of one pint in a three-months-old child caused perforation, the autopsy showing a small rent in the lower part of the intussusception. It may be said that such fatalities are rare, and that in many instances larger amounts and greater pressure have been successfully employed and are usually necessary for success. The writer would reply that what has happened can, and in all probability will, occur again: likewise that dead-house experiments on non-morbid intestinal tissues are so little in relation to the conditions one meets in actual practice that their possible value cannot be discussed here.

The writer would therefore recommend that in those

cases in which he has tried to show the justifiability of a preliminary trial of inflation the attempt should be made as a stage preparatory to immediate opening of the abdomen, if the inflation does not at once overcome the obstruction. All preparations for operation having been made, the patient should be anæsthetized and the outlines of the intussusception carefully studied. A rectal tube should be passed, care being taken that it does not double up on itself. The injected fluid (preferably warm to avoid shock) should then be allowed to run in by gravity, the pressure being gradually raised. It is probably best to have the patient's pelvis well elevated. The operator should meanwhile keep accurate track by the sense of touch of the resulting distention and its influence, if any, on the intussusception. His perceptions of these results should guide his judgment as to the necessary pressure, rather than actual amount, but he must remember that after attaining a hydrostatic pressure of four feet, and even less with infants, he is treading on dangerous ground. Still, even here the conditions pertaining to the individual case must be his chief guide.

If, as a result of the enema, the operator can absolutely recognize by the sense of touch that the intussusception has entirely disappeared, the operation may

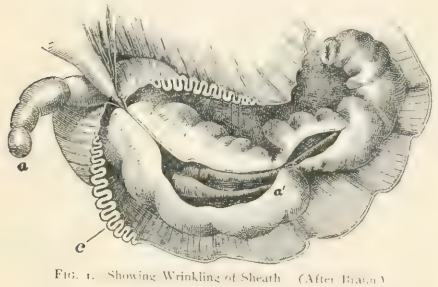

FIG. 1.—Showing Wrinkling of Sheath. (After Braun.)

be *postponed*. The latter term is used advisedly, for the operator should take the attitude that, while he is certain that he has so far been successful, the conditions are likely to recur within the next few hours or days, and all preparations must be kept in readiness. Should the intussusception recur after successful reduction, the writer believes that the abdomen should then be opened at once, lest by further delay the "golden moment" be allowed to pass.

(Braun[92] has called attention to a frequent source of mistaken belief in the sucessful performance of reduction, in that the wrinkling and stretching of the sheath (Fig. 1) allows of extensive variations in the length of the intussusception; for instance, one may have the impression that the intussusception extends only three or four centimetres into the sheath, while direct examination will show that the portion of the sheath involved measures twenty-five centimetres).

The writer declines to discuss means of inflation other than by the force of liquids acting under gravity. Such procedures, while attractive by reason of their ingenuity, are dangerous and less suited to the purposes of accurate observation of results.

Can a comparison be drawn between the relative value of treatment by enemata alone, by enemata prior to laparotomy, and by immediate laparotomy without recourse to preliminary measures? It would seem to the writer as impossible to obtain fair deductions from such a comparison as in any other class of diseases which present varying conditions, calling in some instances for medical, *i.e.*, bloodless procedures, in others for surgical or operative relief. No clinician of wide experience would to-day attempt to show such a contrast between surgical and non-surgical cases of diphtheria, cholelithiasis, appendicitis, etc. Our aim should be to obtain the greatest diminution of mortality, and it would seem preferable to expose one's self to the reproach of having done a needless operation than to that of having sacrificed a life from non-intervention. Therefore it would seem preferable to yield to an excessive desire for certainty, as illustrated by Case 61*a* (Table II.), in which the surgeon, not feeling absolutely certain that the attempt at mechanical reduction had been perfectly successful, performed abdominal section only to find that the intussusception was already reduced.

Treatment by Abdominal Section.—The writer hopes to be pardoned if he takes the liberty of giving a few hints as to the preparations for operations not conducted in an institution. A sufficient number of assistants should be obtained, if such are available, and the duties of each one clearly defined. The house need not be turned topsy-turvy, nor carpets, drapery, curtains, etc., removed except for direct economy. In fact, it is better not to do anything to stir up a dust in the room where the operation is to be performed. The best-lighted room should be chosen, provided it can be well heated if the weather be cool. Sheets, towels, etc., can be properly sterilized by boiling half an hour. It is well to remember that in an emergency even five minutes' boiling gives a tolerably high degree of sterilization. Among other methods of sterilizing the patient's skin is the simple one of scrubbing with green soap and washing off in ninety-five per-cent. alcohol. For the hands * a simple and very effectual method is scrubbing with hot water and soap, rinsing off, and then rubbing the hands and arms with a paste made by taking in the palm of the hand a teaspoonful of washing-soda, adding a crystal of chloride of lime about half the size of the terminal phalanx of the little finger, and adding a few drops of water. Rubbing this mass produces a paste, which becomes smoother with the prolongation of the rubbing. The nascent chlorine thus given off has been proven one of the most powerful germicidal agents in its action on the skin yet discovered. Some boiled water should be used to wash off the paste after three or five minutes' use. The instruments should be boiled for half an hour; a teaspoonful of washing-soda added to the water increases the efficacy of the sterilizing process and keeps the metallic instruments from rusting. Once properly rendered aseptic, neither the hands nor the instruments should be contaminated by touching anything that has not been similarly disinfected. The failure to observe the latter rule is to-day probably responsible for the greater part of the fatal results from sepsis, which has not yet been eliminated as a source of death as a sequel to operation.

Every preparation requisite for the possible performance of intestinal resection and anastomosis should be in readiness, all intestinal sutures properly prepared and at once available if needed.

Choice of Anæsthetic.—The writer could wish that the recorded cases might have furnished some details regarding the choice of the anæsthetic employed, but only few records could be found. Even in the United States, where ether is generally given the preference, chloroform is very largely used to anæsthetize children, and will probably be found the best agent when operating for intussusception in children. The writer believes that not sufficient attention has been given to the temporary stimulant effect following substitution of ether for chloroform, after the latter has been given some time. Usually such a change is made if the chloroform narcosis is not satisfactory, but the writer would urge a trial of a routine mixed anæsthesia, the first half under chloroform, the second under ether.

* [illegible] details [illegible] by R. J. Wel[illegible] on this subject.

Operation.—The incision should be in the median line, and from the onset should be generous, and extended without hesitation if sufficient space is not obtained for ready and speedy handling of the intestines. If no point of definite location of the invagination is known, and the first comprehensive sweep of the fingers over the abdomen reveals nothing, the ileo-cæcal valve should be sought for, and the intestines systematically examined from that point in either direction. If the cæcum is collapsed we know then that our search must be directed upward in the small intestine. The intussusception having been located, it should be examined by direct inspection of its whole extent. The first glance may show that reduction is impossible or unwise. Attempts at reduction are best made in the direction of working away the sheath from the invagination rather than pulling the latter out, such a procedure often causing extensive tears of the gut at some adherent point. To guard against extravasation of fæces, the rest of the intestines and the abdominal cavity should be protected by large gauze pads. If the intestine has been successfully reduced, a close examination should be made of it to determine if any portion is so injured as to impair its vitality. If there is a little doubt as to its integrity, one may employ Hahn's method of surrounding that portion by a gauze packing, over which the sutures of the abdominal wall may be provisionally tied. By such a precaution the general peritoneal cavity is shut off from absorption of septic material from possible sloughing of the intestinal walls, and if perforation takes place it does so under the conditions of an extraperitoneal lesion. Twenty-four hours' observation under such conditions will usually suffice to determine the ultimate fate of the intestine, whether it can safely be returned into the belly or whether further procedures are indicated. The writer was a witness of this treatment in the case reported by Curtis, Case 69, Table II., and can add his testimony to the efficacy of the procedure. While the gut was so isolated, the patient had a free movement of the bowels, showing that the skilful disposition of the gauze, while accomplishing its purpose, had formed no impediment to the free passage of intestinal contents.

Lindemann's case (No. 37, Table II.) is another example of the wisdom of this procedure.

If the intestine cannot be safely or effectively reduced, what shall be our attitude?

The first point to decide is whether the irreducible intussusception is free from septic conditions or sloughing. Great care, experience, and judgment are required to be able to answer this question in the affirmative.

An acute intussusception that cannot be reduced is in all probability rarely solely an irreducible condition—that is to say, it is usually accompanied by lesions of a septic nature, which endanger life both by septic infection *per se*, and secondarily by permitting extravasation of the fæcal contents. If the conditions are such that doubt exists, the wisest course is to treat the intussusception as of the gangrenous variety, for which, as will be shown later, only one broad line of conduct is permissible.

Having determined then that we have to deal with a purely irreducible condition, we have the choice of the following methods:

1. Artificial anus.
2. Entero-anastomosis.
3. Partial resection.
4. Typical resection.

(1) A purely irreducible intussusception presents the only condition in which a primary artificial anus (as a sole measure—see below, combination of resection and artificial anus) is ever permissible. Even here its use must necessarily be limited. In all forms of intussusception not exclusively limited to the large intestine (and such cases are infrequent) the artificial anus is necessarily made in the small intestine. Except for the lower portion of the ileum, an artificial anus in the small intestine is incompatible with the preservation of life except for a very brief period of time. Even in the lower ileum nutrition is seriously impaired and much suffering results from the excoriating character of the fluid intestinal contents. The procedure should therefore be reserved for those cases whose general condition is so desperate that any further procedures must necessarily be followed by death. For the large intestine the indications are much more favorable, and in some cases will constitute the most judicious form of treatment. A decision to limit one's self to an artificial anus, even under these circumstances, must be undertaken with the full appreciation of the after-history of these cases. In these tables only three cures after artificial anus are recorded, and all three required more or less extensive operations to effect such a cure. Among the fatal cases are included three in which life was prolonged for a variable period of time, but these patients succumbing after resection, etc., of the fistula, they are properly classed among the fatal cases. That is, in six cases of artificial anus, in which subsequent operations were found advisable or necessary, the mortality was fifty per cent., and these facts should be given due consideration by the operator before his decision to make an artificial anus is reached.

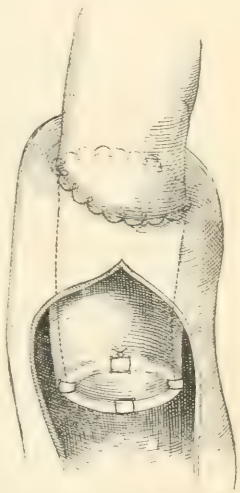

Fig. 2.—Sheath Opened and Invagination Resected. (After Rydygier.)

(2) Entero-anastomosis. By this term we mean the formation of an anastomotic communication between the segments of the gut above and below the intussusception, thus side-tracking the affected portion. This operation may compete with the next two to be described, but not with artificial anus, the latter being reserved for the desperate cases.

Entero-anastomosis may be performed by means of sutures alone, an operation requiring for its proper and speedy performance considerable technical skill, but constituting more nearly the ideal of intestinal anastomosis, or by means of some mechanical device. The Murphy button will here give a very speedy and simple means of reunion, and should doubtless be preferred when time is a very important element. It is to be borne in mind that anastomosis by any mechanical device that must eventually perform the rôle of an intestinal foreign body is not an ideal method.

(3) Partial or atypical resection, or resection of the intussusception through an incision in the sheath.

Various procedures, differing chiefly in minor or technical details, have been described, and to them several operators' names have been appended (Jesset, Barker, Rydygier).

The following may be described as the essential steps of the operation (Fig. 2): Circular running suture securely uniting the invaginated gut to the sheath at the neck; longitudinal incision of the sheath; cross section of the invaginated portion; sutures of

varying nature and extent of the proximal cut edge, especially of the mesenteric portion for the arrest of hemorrhage; extraction of the (now) free portion of the resected intestine either through the longitudinal incision, or, if long and accessible, by the rectum from below; suture of the incision; closure of the abdomen.

For the successful performance of this operation, absence of firm adhesions within the sheath is desirable. The operation under favoring conditions is simple, speedy, and sacrifices less intestine than a typical resection, as the sheath is preserved intact. In one of Mr. Barker's[57] cases the whole duration of the operation was only half an hour.

(4) Resection of the entire intussusception. The performance of this operation for irreducible intussusception will probably occur less frequently with the further familiarity with the last described procedure, the latter being a comparatively recent operation. Before it is undertaken, the reasons for preferring it to the last two operations should be established. These may be briefly stated to be: for entero-anastomosis, hesitation at leaving a considerable portion of the gut to "take care of itself," or (rarely) technical difficulties in performing entero-anastomosis; for resection of the invagination, failure to separate firm adhesions; for either procedure, if there is any suspicion relative to the intestine's non-septic condition.

Treatment of Gangrenous Intussusception.—The writer believes that here the conditions requiring relief are so urgent and so clearly defined that there can be little choice in the methods of operating. The patient must be relieved of the obstruction and of the infection attending gangrene. Remedying the first condition without remedying the second is equivalent to doing nothing at all. To make an artificial anus under such conditions is simply an act of mercy intended to mitigate the sufferings attending dissolution. We are face to face with a desperate condition and one doubly sad, in that in many instances the responsibility for this condition is on the shoulders of some one who ought to have known better. To operate in such a manner and so extensively as to meet the requirements of the condition is nearly always certain to be followed by death; not to do so is to abandon the patient to his fate. It may be objected that death is inevitable in most cases from the existing general peritonitis, which of course no amount of exsection of the intestine can deal with. To this objection the writer would say that cases of diffuse purulent peritonitis do sometimes end in recovery. That they are rarities is freely acknowledged, and the writer's scepticism about many alleged cures of general peritonitis is well pronounced, as many such cases are more probably forms of extensive localized peritonitis. Still, if by operating even only one in a hundred lives is saved, shall we not make the attempt? The chances are not so desperate, however, as the question might lead one to judge. The present methods show a gain in saving of life that could not have been conjectured two decades ago. In 1885 that very careful observer, Braun, could find no record of cure by operation of non-reducible intussusception. The records of these one hundred and forty-nine cases here appended, beginning in 1888, show that nine such cases have been cured by the improvements of modern surgery, whose progress is nowhere more marked than in intestinal operations.

While the experience with the antistreptococcus serum is still too limited to allow of more than a hint as to its possible usefulness, and while realizing that any unduly enthusiastic views may lead to delusions which so easily took possession of the profession regarding other possibilities in the line of antibacterial remedies, the writer nevertheless believes that we should not fail to make use of this or any similarly devised principle of treatment that holds out hopes of supplementary aid in so grave a condition as gangrenous intussusception.

As regards operative treatment the writer recommends only:

1. Resection with immediate union of divided intestine; or,

2. Resection with utilization of divided ends for a temporary artificial anus.

(1) It is thus evident that any method that does not provide for removal of the gangrenous area is rejected. The removal should not be niggardly, the healthy area should be encroached upon to a sufficient extent to insure radical cure. The writer has collected numerous instances in which an apparent hesitation to follow the above recommendation has destroyed the chances of what would otherwise have been a good operation. An example of necrosis of the anastomotic edges is shown in No. 110, Table II. Moreover, resection of a large portion adds comparatively little to the time or difficulties of the operation. Astonishingly large amounts have been successfully removed with little or no influence on the general health. Cases 103 and 104, Table II., are instances of the truth of this assertion. Other examples are to be found in the following:

Rocci and Fantino[58]	310 cm.	ileum.
Köberle	205 "	small intestine.
Hinterstossier[59]	186 "	ileum.
Kocher	160 "	small intestine.
Braun	137 "	" "
Schlange	135 "	" "

TABLE X.

Results of Resection.	No. of Cases.	Cured.
End-to-end suture	12	2
Partial resection	3	0
End-to-end anastomosis (Murphy button).	6	3
Lateral anastomosis and method unknown.	3	0
	24	5

Mortality, 79 per cent.

The cases are too few to venture on any significant claims for the advantages of any one method. The proportion of recoveries (fifty per cent.) with the Murphy button is encouraging, and should certainly warrant a further trial of this method. Undoubtedly the time-saving element is its chief advantage, and the operator with limited experience in intestinal work will in all probability often get the best results with this simple device.

A record of Maunsell's method does not appear in these tables, but his simple device can well compete with the Murphy button. It takes the least time of any of the methods by suture alone, and is free from the disadvantages attending the use of any mechanical aid.

The writer is compelled, though somewhat regretfully, to refrain from a further prolongation of this paper by the consideration of the indications for the employment of the several methods of typical resection.

(2) If after the excision of the gangrenous area we feel that the patient's failing strength will not permit further measures, we can bring the ends of the bowel into the wound (or if preferred into a separate wound), as a temporary artificial anus. These ends should be so placed with relation to the external wound and to each other as to permit ultimately of the easiest methods of repair.

Before closure of the abdomen the operator should convince himself that no second intussusception or other form of obstruction exist. Cases 79, 91, and 112, Table II., show the necessity of such precautionary measures.

As rapidity of operation is desirable, the following method of closure of the abdominal wound is given, as this part of the operation is often less in keeping with the desired end than the rest of the operation. Transfix all the layers with a Peaslee needle, entering in the skin on one side (the fascial layer being drawn well forward by the assistant) and passing through the peritoneum. The needle then transfixes the opposite side in reverse order, emerging at the skin. A piece of silkworm gut is threaded in the eye and the needle withdrawn. Should the condition allow the expenditure of more time, the peritoneum may be sutured separately with catgut, and not included in the other sutures. Should the condition be very good, the fascial layer may be united separately to guard against hernia. In aseptic cases, interrupted buried silkworm sutures have given the writer most gratifying results, both immediate and remote.

Shock—After-Treatment.—The writer does not believe that the degree of shock exhibited by children is so intense as usually supposed. We must differentiate between the shock resulting from the condition necessitating operation and that from the operation proper. Children bear serious operations on the osseous system with no more depression than is exhibited by adults, on condition that the amount of hemorrhage is small. While an explanation of the source of shock does not banish the condition as we have to meet it, it emphasizes the importance of prophylaxis—not to let the morbid conditions exist or progress to a condition of shock which *per se* is hopeless.

Much can be done, however, to tide over a condition of shock, and attention to minor details may prove the turning-point in obtaining a successful result after operation. The chief stimulants in their order of importance are heat, alcohol, and drugs. Loss of heat at any stage must be zealously guarded against, and in the operation contact with moist cloths, irrigating fluids, etc., avoided, owing to the cooling effects of evaporation. In very pronounced shock alcohol should be given hypodermatically, as the state of the circulation will probably allow but little absorption by the rectum. Of drugs, strychnine hypodermatically is probably the most efficient. Camphor dissolved in olive oil is a most valuable subcutaneous agent. Stimulation by drugs requires the exercise of great judgment and accurate observation of their action. The writer feels quite sure that a not insignificant proportion of operative cases terminate fatally from the injudicious administration of dangerous stimulants.

The injection of warm saline solutions into the circulation, either directly into a vein or subcutaneously, is no longer limited to the treatment of shock dependent on hemorrhage. While never having had occasion to resort to it in children, the writer would urge that a trial of this procedure be made in combating the shock in operations for intussusception in children. It should not be used as a last resort, nor should its accomplishment interfere with the operator; to some competent assistant should, if possible, be delegated the sole duty of performing it whenever called for. In the first few hours after recovery from the anæsthetic the pain and restlessness may compel one to give some form of opiate, but in general it is best withheld in order not to confine the bowels. The profession is now very nearly a unit on the advisability of obtaining early and free movements of the bowels after abdominal operations, and the treatment is of especial value if there is any suspicion of peritonitis. Dr. A. J. McCosh,[78] of New York City, is so convinced of the wisdom of the above that he has adopted a radically certain method of obtaining the desired result. Before closing the abdomen he injects an ounce or so of a saturated solution of Epsom salts directly into the intestine, a large antitoxin syringe being used. The puncture is closed with a Lembert suture. On recovering from the anæsthetic the patient is furthermore given ten grains of calomel.

HYSTERICAL APHONIA.

By SANGER BROWN, M.D.,

CHICAGO, ILL.,

PROFESSOR OF DISEASES OF THE NERVOUS SYSTEM, POST-GRADUATE MEDICAL SCHOOL; PROFESSOR OF MEDICAL JURISPRUDENCE, RUSH MEDICAL COLLEGE; ATTENDING NEUROLOGIST, ST. ELIZABETH HOSPITAL; ATTENDING NEUROLOGIST, ST. LUKE'S HOSPITAL; MEMBER OF THE NEUROLOGICAL SOCIETY, LONDON, ENG.; NON-RESIDENT FELLOW OF THE NEW YORK ACADEMY OF MEDICINE; FELLOW OF THE CHICAGO ACADEMY OF MEDICINE, ETC.

My apology for calling atention to a mere symptom is that hysteria presents such an endless variety of symptoms that one can hardly attempt to take them all together within the compass of one short paper. I invite attention to hysterical aphonia because, while it is not one of the most frequent symptoms of hysteria, it is one of the most conspicuous when present, and though in a large majority of the cases no very great difficulty is met with in attempting to diagnose it, yet there are cases which have baffled the general practitioner successfully for a number of years. I hope I may be excused if I briefly discuss this symptom somewhat as I would do if it were regarded as a disease, because I am accustomed to discuss medical topics in somewhat of a stereotyped way.

Hysterical aphonia has been pretty clearly recognized and described for a century at least; its etiological conditions are practically the same, of course, as are those of the disease of which it is a symptom, namely, hysteria.

In quite an extensive search of the literature of the subject, the youngest case that I have encountered was one occurring in a girl of nine, while the age of the oldest was that of a woman of seventy-four years.

In regard to the symptomatology and etiology, at least two fairly distinct types are found; first may be considered that type in which aphonia is merely an accompaniment of many other pronounced stigmata of hysteria, such as hysterical pains, hemianæsthesia, vomiting, etc., occurring either with or without any apparent exciting cause. In such cases it frequently happens that the aphonia is not entirely pure; that is, for hours together, when the other symptoms are most complained of, the patient may be unable to raise the voice above a whisper, but in the intervals may be able faintly to phonate now and then a word or syllable. The second or pure form of aphonia, however, is that in which this symptom occurs suddenly with or without an exciting cause, continues for a longer or shorter time, and constitutes the sole evidence of hysteria.

In the impure type the aphonia may be among the first symptoms to appear, or it may show itself only after other symptoms have been present for weeks or even months. It may commence as a transient hoarseness, worse when the other symptoms are worse, or as hoarseness associated with an ordinary cold; finally, complete or almost complete aphonia supervenes, which may last from several days to several weeks or even months.

In the pure type, as already stated, the aphonia usually develops suddenly, with or without exciting cause. For instance, the patient comes down to breakfast in his usual health and spirits, and finds, much to his surprise, that he cannot raise his voice above a whisper, or very rarely he may be entirely mute; or the symptom may develop suddenly as the result of a severe emotional shock. The influence of an emotional shock will vary directly with the susceptibility of the individual's nervous system at the time of receiving the shock. This point is of the utmost importance in estimating the influence of emotion in producing disturbance of any function of the nervous system.

Many of these cases recover spontaneously and even suddenly after a few weeks or months, with or without treatment; others remain uninfluenced by treatment, the symptom persisting steadily for years. To be sure there are many mixed cases.

A great many methods have been enthusiastically put forward as successful in the treatment, more especially of the pure types above referred to, but in the last few years it has been pretty clearly demonstrated that they owed their success entirely to the influence of the suggestion with which they were accompanied; and in my opinion any method depends for its success upon the facility which it affords the patient for concentrating his efforts upon an attempt to phonate. Hypnotism has been successful in a number of instances, but not more so than the various forms of electricity, more particularly faradism, applied to the larynx, sometimes by a peculiarly shaped electrode applied internally, and at other times simply applied externally

A method advocated by Oliver a few years ago attracted considerable attention and became known as his method, and has given excellent results. His plan was to pinch the posterior part of the arytenoid cartilages between the thumb and index finger, and thus produce an approximation of the vocal cords, at the same time vigorously shaking the larynx and calling upon the patient to make an attempt to phonate, assuring him positively of his ability to do so. At first only vowel sounds were attempted, and gradually the pressure and shaking were diminished, until the patient was able to phonate without assistance. In case any particular sound was not satisfactorily produced, the pressure and shaking were reapplied.

A third very ingenious and successful method consists in first getting the patient to cough, which in nearly every case can be accomplished; having done this, then have him cough and at the same time pronounce the different vowel sounds, and thus convince him of his ability to phonate. It is probable that in all pure cases any of these methods, if applied with suitable suggestion on the part of the operator, would be successful; but in the cases in which the aphonia is associated with other marked symptoms of hysteria, it is doubtful if complete and lasting success will be attained until the other symptoms have in a great measure subsided, and to this end it is often necessary to improve the patient's general health.

I will now describe some cases which fairly well illustrate the different types which I have alluded to above.

As representing the first type, I will quote the case of a policeman, aged forty, of good habits, robust physique; his family and personal history are good, and he could not fairly be regarded as a man of nervous temperament. Though he received some quite severe flesh wounds in the Haymarket riot, in the main his duties have not been severe, neither have his personal or family relations been of such a nature as to cause him much anxiety. About three weeks before admission to the hospital, while travelling his beat, he felt a peculiar sensation, something like numbness but difficult to describe to his satisfaction, commence in the radial side of the hand, extend to the thumb and index finger, and thence at times shoot up the shoulder. He continued his work until about five days prior to ad-

mission, when he suffered frequent paroxysms of severe pains in the left side and chest, accompanied by nausea and vomiting. During these attacks he could not speak above a whisper, and during the intervals he was very hoarse. Finally, when admitted he was pretty constantly and completely aphonic, though occasionally a syllable would be faintly phonated. Movement of the legs was normal, knee jerks were very lively indeed, and there was severe general jerk of the body when the patellar tendon was tapped; vision and the visual fields were normal, but there was complete absence of pain reaction to pin pricks and pinching over the entire left half of the body, including the tongue, gums, and inner surface of the cheeks, while sensation in the right half of the body was normal. Positively assured that a strong current of faradism would restore his voice and relieve his pain and vomiting, after the first application he phonated clearly and was for the time entirely relieved of the pains in the chest and nausea. After a few daily applications he said he felt entirely well, with the exception that occasionally he had slight pain through the chest and still a little numbness in the radial side of the hand. He returned to the hospital several times for treatment after resuming his duties, but in the course of two or three weeks from his admission he had entirely recovered. This, then, was a case of an impure hysterical aphonia occurring in connection with other well-marked symptoms of hysteria, without any apparent exciting cause.

The next case is that of a woman, thirty-one years of age, the wife of a professional man. She has had one healthy child, has correct habits, a good family history, and had always enjoyed excellent health up to two years ago, when a railway train upon which she was a passenger ran into a culvert while going at a high rate of speed, and was stopped so suddenly that all the seats were torn loose and bunched in the forward end of the car. The patient was quite severely bruised on the posterior aspect of the left hip and thigh, and received several slighter bruises on various parts of her person. No one was killed, or in fact more severely injured than herself, so the mental shock was only such as was incident to the sudden confusion and temporary anxiety for the welfare of her child, who was with her but sustained no injury. Almost immediately after getting out of the car she felt weak and dizzy, and vomited. The accident occurred at about 1 P.M., and a few hours later she again boarded a train without assistance and rode several hours till she reached her destination. She had in the mean time suffered intense and increasing pain in the legs, and had been able to walk only by putting forth a great effort. She slept several hours after a full dose of morphine, but when she awoke the pain in her legs was as severe as ever; she felt greatly prostrated, was unable to stand both on account of pain and weakness in the legs, and was unable to speak above a whisper. She continued in this condition for two weeks, when she was seized with severe hysterical convulsions lasting several hours, with unconsciousness and opisthotonos. It was six months before she could walk without support, and about six weeks before she spoke above a whisper. Her recovery from aphonia was not then sudden and complete; at first only a word or syllable was phonated, the remainder of her speech being whispered; then she gradually improved so that her voice only sank to a partial or complete whisper when she was tired. She had suffered many attacks of complete or partial aphonia, always associated with pain and weakness in the legs, and lasting from a few days to a few weeks, between the date of the accident and my examination several months ago. At that time she had been suffering several days from an exacerbation of symptoms like those already described, which she thought had been brought on by overwork and taking cold. For several weeks previous to this exacerbation she had been better than at any other time since the accident, was comparatively free from pain, could walk alone in the street, and her voice was comparatively clear and strong.

When examined she was in bed, complaining of pain in the legs, back, and head; of vertigo and nausea on movement, and inability to walk. She conversed entirely in whispers at first, but later, when her interest became aroused, now and then a word or two were phonated weakly and hoarsely. She said she felt no pain, and showed no signs of feeling any when pricked with a pin ever so deeply or pinched in any part of her body. The field of vision for white was reduced to the fixation point. The knee jerks were very lively, and when the tendon was tapped the whole body responded with a violent jerk. The body was well formed and well nourished, loss of appetite and nausea notwithstanding. In bed the arms and legs could be moved voluntarily in any direction, though she declared she was entirely unable to walk, both on account of pain and weakness. I saw this patient only once and then in consultation, and cannot say anything regarding the results of treatment, but it illustrates a type in which an impure form of aphonia is associated with very marked symptoms of hysteria developed by an exciting cause.

The next case may be regarded as illustrating the most common type of pure hysterical aphonia, not associated with any other hysterical stigmata. Miss A. A——, aged twenty-nine, attendant in hospital for insane; nervous temperament, very competent, good general health. She had been employed several months in convalescent ward, and was not under a strain of any kind, when on rising one morning after sleeping well and feeling in her usual health, she found she could only whisper. She declined treatment and the attack lasted five weeks without mitigation, when it suddenly and permanently disappeared, the patient having attended to her work as usual in the mean time and remained in her good general health. She had previously suffered two similar attacks at intervals of several years, from which she had recovered spontaneously, and for which she could assign no cause.

The next case is that of a young man, aged twenty, farmer's son, intelligent, industrious, of correct habits, fond of company, and not notably nervous. His family history is good, and he has always enjoyed excellent health, rarely having even a cold. When he was eleven years of age his father called him as usual one morning to rise, but for some reason he went to sleep again, so that his father called him a second time, speaking somewhat sharply. From that moment until he entered my office, nine years later, according to his own testimony and that of his family and numerous friends and acquaintances, he had never uttered a sound of any kind; in fact, had been absolutely mute. His playmates, when he was still a child, would throw him down and tickle him, trying to make him laugh; his face on such occasions would undergo the usual contortions, but no sound was emitted. On still more careful inquiry, it appears that occasionally a very slight sound had been emitted when he was in the act of clearing his throat, but so far as I could learn he had never been heard to cough so that he could be heard more than a few feet distant, and some members of the family in which he had lived for years were positive that they never heard him utter a sound of any kind; his communications were all made by writing. His hearing was quite acute. Movement, the reflexes, the visual fields, vision, and sensation were all entirely normal.

I had a laryngoscopic examination made by my distinguished colleague, Prof. E. Fletcher Ingals, who

succeeded in getting a satisfactory view of the vocal cords only after the use of cocaine; they were found to be normal in every respect, and in making the manipulations necessary to secure a satisfactory examination the patient coughed slightly. After thoroughly arousing his interest and attention by a rather minute and spirited dissertation upon the mechanism of speech (which of course he could not comprehend, but which convinced him none the less of my great skill), I assured him, with as much dramatic force as I was able to assume, that I could cure him entirely by the use of electricity, and very speedily too. I then proceeded to apply a strong faradic current to the larynx, only for a few moments, by placing a disc-shaped electrode, about one and one-half inches in diameter, on each side of the organ, assuring him beforehand that after I had done this he could phonate the vowel sounds, and that as these were the basis of articulate speech, it would be necessary for him to learn to phonate them first in regaining his ability to speak. Immediately after this procedure he was able to phonate the vowel sound "e" after me; to be sure it was very weak, nevertheless distinct; whereupon I terminated the *séance*, assuring him that the victory had been won. After this I gave him a daily treatment, and the progress was very rapid. He was soon convinced that if he said "e" he could say "eat," and if he said "o" he could say "go," and so on; in less than a week he could carry on ordinary conversation in rather a low tone of voice. He was then assured that in the course of a week more his voice would gradually strengthen until it would finally be as strong as that of the ordinary individual, and this he found to be the case. This was six months ago, and he has continued well ever since.

This case deserves some comment on account of the youth and sex, perhaps, of the individual in whom it occurred, but more particularly on account of nine years' duration of unbroken mutism. He had seen a great many practitioners, none of whom, so far as I can learn, had made a correct diagnosis, probably because it was so difficult to get a satisfactory view of the vocal cords, and after the case had lasted two or three years without interruption a practitioner might naturally assume that it was not one of hysterical aphonia; but really, with the history of the onset that I was able to get, the excellent state of general health ever since, and especially when the vocal cords were found to be entirely normal, there was no difficulty in making the diagnosis.

A somewhat careful examination of the literature has not enabled me to find a case that was anything nearly parallel to this in point of degree or duration. I found several cases of hysterical mutism which had lasted for several weeks, and one—that of a young woman of twenty—which had begun as simple aphonia and continued as such for several months, when it lapsed into a condition of mutism likewise lasting several months, and which finally recovered by suggestive treatment. In my opinion the efficacy of the treatment in my case was due entirely to suggestion.

The pathology of the disorder is, of course, the same as that of the other manifestations of hysteria. It is hypothetical, but most pathologists are substantially agreed upon the hypothesis, which is this: The parts of the cerebral cortex which normally preside over the various disordered functions become inactive, to the extent that they no longer respond to the behests of the will as before; accordingly in aphonia the cortical centres from which in health the motor impulse proceeds to the muscles concerned in phonation are no longer excited to activity by the volition of the patient.

Within the last year or two Lepine and Duval—each claims priority by several months—have elaborated a hypothesis to the effect that neurons, when in a state of functional activity or potentiality, are expanded so as to be in physiological contact with such other neurons as properly participate in any particular function. During rational sleep or hysterical paralysis they are contracted, and physiological contact is broken. This theory assumes that the neurons, which are in fact protoplasmic cells, undergo amœboid movements, and experiments have been made upon frogs which appear to demonstrate the possibility of such movements on the part of neurons.

The effect of suggestion in the treatment of hysteria according to this theory might be rationally accounted for by assuming that it enabled the patient to exert an extraordinary amount of will power, resulting in the necessary expansion and contact of the neurons concerned.

A W[illegible]

Progress of Medical Science.

Skiagraphing the Arteries. — At a recent meeting of the Pathological Society of Manchester, Dr. Raw explained to the society a method he had adopted for skiagraphing the arteries. He said that, when trying to examine a fracture which was enveloped in a thin layer of plaster of Paris, he found it quite opaque to *x*-rays. The idea then occurred to him that the vessels (arteries) might be reproduced in the skiagraph by injecting them with a somewhat similar substance. Accordingly, when the next opportunity occurred, he injected post mortem a solution of calcium sulphate and carmine into the femoral artery and then took skiagraphs of different parts of the body. He illustrated his remarks by exhibiting several pictures showing the arteries perfectly, even to the most minute anastomoses. In fact, so opaque was the substance that the arteries actually showed through the bones. Dr. Raw also exhibited a twenty-four by eighteen inch bromide print of a child, showing all the arteries of the body injected.

Recovery from a Large Dose of Silver Nitrate. —At a recent meeting of the Leeds and West Riding Medico-Chirurgical Society, Drury (*Lancet*, May 15, 1897) related that while pencilling the throat with a stick of silver nitrate in the course of an attack of tonsillitis, the stick became detached and slipped into the œsophagus. There were localized pain in the gastric region and a strong conviction that death must soon follow. Immediately a frothy foam welled up in large quantities, forcing its way through the mouth and nostrils, staining handkerchiefs and the bed linen. There was an irresistible feeling that the pencil was lying impacted in the gullet. Upon the urgent request of the patient a probang was passed. Mustard was given in large quantities and vomiting induced. Some time afterward common salt was given. Careful search in the vomited matter failed to disclose the presence of any of the pencil that might have remained undissolved. Collapse and great exhaustion followed. For some days a milk diet was rigidly observed. All food, especially if sweetened, had a salty taste. There was no further vomiting, but constipation was pronounced. The temperature became subnormal and the earlier symptoms disappeared. During the following two weeks there was well-marked desquamation over the whole of the skin. In the subsequent twelve months there were many indications of dyspepsia, but some of these had been present in a milder degree previously. The pencil was composed of four per cent. of potassium nitrate and the remainder silver nitrate. There was little fluid or food present in the stomach at the time of the accident.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, July 17, 1897.

PTOMAIN POISONING.

THE recent wholesale poisoning from the eating of ham sandwiches at a picnic in Wappinger's Falls calls attention to a source of danger in similar gatherings which should not be lightly considered. Although it is currently reported that the cause of the trouble was the creation of soluble salts of copper, due to the use of an unclean copper vessel in which the ham had been cooked, it is nevertheless quite evident that ptomain poisoning was at the bottom of the trouble. It may sound strangely to such as have not given the subject serious attention to say that copper utensils are not specially dangerous for culinary purposes, but such we believe to be the fact. For ages this particular metal has been used without markedly detrimental results, and many authorities have gone so far as to maintain that as yet no well-authenticated cases of copper poisoning have been recorded. "It is a curious fact," says Professor Brouardel, of Paris, in his interesting and instructive book on "Death and Sudden Death,"[1] "that this idea of poisoning by copper owes its origin to Jean Jacques Rousseau. You know how fashionable his ideas were for a certain period; you know the infatuation they created. It is not very wonderful, therefore, that the opinions he professed on the injuriousness of copper should have gained acceptance. Nevertheless, it has not been forgotten that the ancients did their cooking in copper vessels. The tinning of copper saucepans was only introduced, into the west of Europe at any rate, by the gypsies, who were the first to line the interior of copper vessels with tin more or less pure. Lastly, at all times and even to-day, certain culinary preparations are made only in untinned pans. Such is the case with preserves, which have never poisoned anybody yet, and yet which are capable—for example, when preserves of currants are made—of producing soluble salts of copper. We know now that copper utensils are quite harmless, so long as they are kept in good order." From these facts we are led to infer that the alleged cause of the food poisoning in the Wappinger's Falls outing was in all probability founded more on popular belief than on scientific fact.

On the other hand, cases of ptomain poisoning from tainted food ingredients are very common. The numerous instances of severe prostration, vomiting, and high temperature after partaking of picnic ice cream are instances of this sort. It is much easier to understand that the ham, either before or after it had been cooked, might have become partially decomposed during the preparation into sandwiches, than that the copper kettle should have been the leading factor in producing the results. Then, again, it is not positively stated that all the meat was cooked in the same vessel; neither, so far as can be learned, was the presence of copper salts demonstrated in the food product or in the vomited materials of the patients.

It is well known that under certain conditions of high temperature, increased humidity, and disturbed electrical tension albuminoid foods are apt to take on rapid chemical changes, resulting in the production of numerous well-demonstrated cadaveric alkaloids. It is not necessary that disagreeable odors should be evolved in all cases to verify the existence of such changes, neither is the presence of the latter always manifested by the sense of taste. Another fact of great importance is the transitory and volatile character of different ptomains during different stages of decomposition. The same meat which may poison one day may be relatively harmless the next. A very interesting verification of this fact is given by the same author, Brouardel: "Two pork butchers (in Lille) had purchased a pig, but whereas the customers of one all fell ill after eating sausages made of the flesh of one-half of the carcass, the customers of the other remained absolutely free from anything of the sort. It could not, therefore, be the previous condition of the pig that was to blame; the shop, the stall, and the workshop of the butcher were clean and in good order. It was necessary to search farther. The pig had been killed on a Friday, a day on which pork-butchers' shops are closed in Lille. The meat had been exposed for sale on Saturday, May 19th, and Sunday, May 20th, and none of the buyers suffered at all. Those, however, who bought sausages on Monday and Tuesday (May 21st and 22d) were all taken ill, and four of them died. The law interfered and the sausage meat was withdrawn from sale on the Wednesday. On that day and the day following, the pork butcher, not wishing to lose his goods, fed himself and his household on the remains of the pork, and no mishap followed." Certainly these are significant facts as bearing on the probable cause of poisoning in Wappinger's Falls.

[1] "Death and Sudden Death," by P. Brouardel. New York, Wm. Wood & Co., 1897.

CYCLING FROM THE STANDPOINT OF HEALTH.

ANOTHER note of warning has been sounded in regard to the possible evils of cycling. Under the somewhat ambiguous title of "The Hidden Dangers of Cycling," an alarmist article recently appeared in the *National Review*, pointing out some of the risks of injury to health to which bicyclists are liable, and darkly hinting at others likely to be incurred. The chief novelty of the article lies, however, in its suggestion as to cause. The author, Dr. Shadwell, has written

on the subject at various times, so that his views carry a certain amount of weight. To him also belongs the distinction of originating the term "bicycle face," which has been so generally adopted to express the anxious, strained look many bicyclists wear. The hidden dangers of the exercise, in the opinion of Dr. Shadwell, threaten women, and more particularly young women, and the prediction is made that in the course of a year or two quite a different story will be heard concerning the health-giving properties of cycling. Dr. Shadwell says: "Sufficient time has not elapsed since it became a general practice to bring the disadvantages to light—to the light, that is to say, of public recognition. Medical men have been kept studiously in the dark on the subject. They always are in like cases. The successes are blazoned forth, the failures concealed. So with bicycling. The fortunate persons who have derived benefit as well as pleasure from it volubly recount their experiences to the largest audience they can command, and the chorus of praise waxes louder by reiteration. Those who have suffered conceal the fact as far as possible, and especially from the doctor, for fear of being forbidden their beloved 'bikes.' That is noticeably the habit of young women, who are the chief sufferers."

A few cases of serious breakdown that came under the author's notice are cited, one of a girl who developed exophthalmic goitre as the result of a long ride, and which became chronic. Appendicitis and internal inflammation are also laid to the charge of the wheel. But the complaints to which the writer in the *National Review* chiefly wishes to draw attention are the various forms of ill-defined nervous effects resulting from even a moderate use of the bicycle. The contention is made that the harmfulness of the exercise does not consist so much in excess as in the strain on the nervous system. The proposition is laid down that overexertion is quite inadequate to explain the effects from which many cyclists suffer. The symptoms are essentially nervous, and point to a cerebral and not a muscular origin. The theory brought forward as to the cause is not the saddle, the vibration, or mechanical defects of the machine, but its instability and the constant strain required to keep it in an upright position. Dr. Shadwell holds that this incessant tension is that which tells upon the nerves.

The arguments introduced in this article are not sufficiently definite, however, to be of use in drawing any conclusions. Taking into consideration the immense number of persons who nowadays ride a wheel, it would be remarkable if among the number there were not some whom cycling did not suit and some to whom it was decidedly harmful. Unless statistics can be given clearly showing that to a fair proportion of riders the exercise is pernicious, a vague statement of hidden dangers will deter but few. That the nervous system is affected by the exercise is perfectly true, but here again the question of constitution and temperament comes in. Some can ride and experience no nerve trouble, some suffer slightly, while there are others to whom continued riding means a complete shattering of the nervous system. The anticycling idiosyncrasy does exist, but those with whom it is present must be aware of it, and if wise will use corresponding caution. The question of harm resulting from nervous tension has been greatly exaggerated; cases of complete or even partial breakdown from this cause are comparatively rare, probably fewer than in the old cycling days. In bicycles as they are made now, with better saddle springs and the pneumatic tire, vibration has been reduced to a minimum and the tremulousness that used to exist after riding one of the earlier machines has practically ceased to occur. It should not be forgotten that the effect of bicycle exercise on health has already been very fairly tested as regards men. In England cycling has been in vogue for twenty-five years; ten years ago there were thousands of riders in that country, and if the consequences had been as disastrous as its opponents endeavor to prove they must be, the truth would have been brought to light ere this.

Various theories have been advanced to account for cycling affecting the nervous system in the way it does, but none of these explanations is quite satisfactory. That it lies wholly in the action of balancing is certainly not the case. Naturally with an unpractised rider the effort to keep in an upright position will produce considerable nerve tension; on the other hand, to the expert balancing has become as automatic an action as walking or running, and the strain will be infinitesimal. Riding in crowded streets, on a rough road, down a steep hill, or under any circumstances when the senses of sight, touch, and hearing must be continually on the alert, would seem more likely to have a harmful effect than the act of keeping the equilibrium to one who is a master of the machine. Cycling with women has not yet received the test it has undergone with men, but the time has been long enough to prove that on the whole the exercise is decidedly good for them, and the bogy of hidden dangers need spread no alarm among their ranks. A woman organically sound can, under proper conditions and using ordinary precautions, cycle with as little dread of bad results as a man, and so long as she keeps strictly within the limits of her endurance, for pleasure and health and not for emulation, will certainly benefit. Long rides and century runs can do no good and probably may do harm. Hill climbing should be avoided as much as possible, as it puts too great a stress on the large abdominal muscles, and a woman, with her physiological peculiarities, should not submit herself to an undue strain. In the case of anæmic girls cycling usually acts like a charm. The general tonic effect of an outdoor life and the change of thought and scene have an invigorating action on the entire system, and all the organs of the body participate in this beneficial result.

The fact that there are dangers connected with cycling cannot be denied; these, however, are not hidden ones, but are more or less palpable to every observer. It may be said that there is danger in teaching the practice to the quite young. Properly cycling should not be carried on to any extent while the body is undergoing development. Any valvular disease should be an absolute bar to cycling, as the heart is the organ principally exercised. Acute inflammation

of the genital organs should forbid the use of the machine to women, although the exercise is often beneficial in chronic cases of uterine disease. The question finally resolves itself into one of moderation or excess, and the personal equation in this respect is variable. A healthy man may be able to do one hundred or one hundred and fifty miles without exerting himself, while another to all appearances equally healthy should not do more than forty or fifty. Cyclists are too apt to be carried away by the spirit of emulation, and when they do so with riders of a superior capacity they must expect to suffer. Each cyclist should be a judge of his or her own capacity.

THE DOCTORS PUZZLED.

No headlines to a column in the daily newspapers describing a rare disease, a complicated operation, a girl with scleroderma, or a boy with hiccough, is complete without the large-type announcement that the doctors were perplexed and all at sea. This must delight the reader or the reporter would not put it in. He knows nine times out of ten that the physicians understood the case perfectly, and that there was nothing very puzzling about it. Indeed it almost always happens that in the interview with the chief physician, which comes at the end of the story, it is shown that he has frequently seen such cases and knows all about them. Now it is not pleasant for a physician to read every day in his morning journal that his colleagues are being "puzzled" over something or other. It is a reflection which he mentally resents. Lawyers and ministers don't get puzzled. At least the papers never say they do. It is clearly the duty of the physician interviewed, in the interest of the profession at large, to make it a *sine qua non* that if his views are published there shall be no caption indicating that he himself or any others connected with the case were puzzled.

A CRAZY WORLD.

If the crazy Diogenes were alive to-day, he might well light his lantern and set out in quest, not of an honest man, but of a sane one; and if we may believe all who venture to pronounce upon the subject, his search would be a laborious one indeed. We all know, of course, for the masters have told us, that most great geniuses are insane; and the great geniuses, if questioned, would not hesitate to tell us that the inappreciative vulgar herd is mentally incapable of comprehending their sublime flights. Nordau has proven beyond question, to himself at least, that nearly every one of any rank in letters or art is a degenerate, and the degenerates have answered with a *tu quoque* argument which is entirely satisfactory to themselves. The antivivisectionists have asserted that those who experiment upon animals are really sexual perverts, and a writer in one of our contemporaries has retorted that these intemperate opponents of scientific progress are downright insane. The learned, we dare not say sane, editor of another of our contemporaries has ventured the opinion that a writer in the MEDICAL RECORD is mentally unsound because he mildly criticised the action of the Society for the Diversion of Public Funds to Private Uses. The German Emperor has been called insane because he pinches the legs of his guests or trips them up with his sword. The Sultan is insane because he has a harem and seems to favor the killing of his Armenian subjects, and Gladstone is in his dotage because he thinks the so-called Christian powers of Europe ought not to approve of such diversions. Bryan is insane because he wants a silver standard, and the majority of the voting population in the country is insane because it doesn't want it. And we are acquainted personally and by reputation with a great many people who do not think as we do, and are necessarily insane for that reason. We are getting discouraged, for what can we, the only mentally sound in this vast bedlam of degenerates and maniacs, do to prove to these lunatics that we *are* the only sane!

News of the Week.

Obituary Notes. — REV. J. B. MACOOL, M.D., of Elizabeth, Pa., died on July 3d, of congestion of the brain. He was a graduate of the Western Pennsylvania Medical College.—DR. WILLIAM C. WEY, of Elmira, N. Y., died at his home in that city on June 30th, at the age of sixty-eight years. He was a graduate of the Albany Medical College in the class of 1849.

"The New Orleans Medical and Surgical Journal" announces in a few modest words the completion of the first half-century of its existence. The journal was established in 1844, but, as its publication was suspended during the civil war, it only now celebrates its semicentennial. We congratulate our esteemed contemporary, and wish it many more jubilees.

A Scientific Explanation of a Lamentable Occurrence.—Probably the change of climate from the seashore to the more relaxing and debilitating atmospheric conditions at Poughkeepsie had much, though not all, to do with the collapse of the Harvard crew in the late university boat race. An exposure of three weeks to such a change is either too long or not long enough.—*The Boston Medical and Surgical Journal.*

The New Jersey State Board of Medical Examiners.—Drs. G. F. Wilbur, of Asbury Park; A. K. Baldwin, of Newark; and Edwin De Baun, of Passaic, have been reappointed members of the State board of medical examiners of New Jersey for a term of three years. At the annual meeting of the board the following officers were elected for the ensuing year: *President*, Dr. G. F. Wilbur, of Asbury Park; *Secretary*, Dr. E. L. B. Godfrey, of Camden; and *Treasurer*, Dr. A. Ubelacker, of Morristown.

Street Cleaning in Rochester.—The Pathological Society of Rochester, N. Y., has taken action on the condition of the streets in that city. It urges the paving of streets with brick, stone, or asphalt, laid over cement or concrete foundation. In the matter of

cleaning it has adopted a resolution that the method of cleaning by constant manual sweeping and gathering of accumulated dirt and refuse in bags is the most sanitary, and that the use of sweeping machines which raise a cloud of dust should be discontinued. It urgently requests the city officials to inforce the ordinances against the littering of streets with ashes, garbage, etc.

The Wisconsin State Medical Board.—Governor Scofield, of Wisconsin, has appointed the following seven physicians to compose the new State medical board created by act of the legislature last winter: Drs. Walbridge, of Milwaukee; Bell, of Beloit; Ourrens, of Two Rivers; Dale, of Oshkosh; Forsbeck, of Milwaukee; Ludwig, of Richland Centre; and Quigg, of Tomah.

The Southern Empire State Medical Association of Georgia.—The fourth annual meeting of this flourishing association of colored physicians and surgeons was held in Macon on July 1st and 2d. The following officers were elected for the ensuing year: *President*, Dr. E. E. Green, Macon, Ga.; *First Vice-President*, Dr. A. L. Falkner, Macon; *Second Vice-President*, Dr. R. E. Grier, Albany; *Treasurer*, Dr. J. R. Porter, Atlanta; *Secretary*, Dr. H. R. Butler, Atlanta; *Board of Censors*, Drs. C. McCarthy, Macon, A. H. Harris, Athens, and J. T. Shuften, Macon; *Executive Committee*, Drs. G. S. Burrus, Augusta, W. A. J. Mosley, Thomasville, W. H. Harris, Athens, S. P. Loyd, Savannah, and H. R. Butler, Atlanta, chairman. The meeting in 1898 will be held at Americus.

Laryngological Section of the Moscow Congress.—Dr. J. W. Gleitsmann writes that at a special meeting of the Oto-Rhino-Laryngological Society of Moscow, held on the 21st day of June, 1897, it was decided that a bureau should be instituted for the convenience of members of the twelfth section of the Twelfth International Medical Congress (otological and rhino-laryngological section). The object of this bureau will be to give all information needed, not only as to matters concerning the congress, but as to all other matters where our visitors may require assistance or information. This reference bureau will be open from 7 to 9 P.M., from the 13th to the 19th of August, in the Doctors' Club (Bolshaya Dmitroffka), and during the meetings in the room of the twelfth section (*b*, laryngo-rhinology).

The Medical-Charity Abuse in Iowa.—Drs. E. F. Clapp and C. M. Hobby, of Iowa City, have issued a circular relative to an appropriation by the board of regents of the University of the State of Iowa, of nearly $150,000, for the construction and equipment of a hospital, the use and control of which is to be restricted to members of the faculty of the medical department of the State University. It is said also that any persons will be received for treatment in the hospital provided they pay their board and reasonable fees to the physician or surgeon in charge. "Thus," the circular reads, "the State, in behalf of a few individuals connected with the faculty of the medical department of the university, enters into competition with every general practitioner and every hospital and sanatorium in the State; also offering to furnish a set of operating-rooms and all special appliances to the members of the staff without expense to them, thereby giving them great advantages in competition with the large body of the medical profession who have no such extraneous aid." The writers ask for legislative enactment forbidding the admission of any patient who is able to pay for his or her treatment at home or in a private institution; and also providing that no member of the hospital staff shall receive any compensation for his services or receive any pay or gratuity from any patient admitted to the hospital.

The American Association of Obstetricians and Gynæcologists will hold its tenth annual meeting at Niagara Falls, Tuesday, Wednesday, Thursday, and Friday, August 17, 18, 19, and 20, 1897, under the presidency of Dr. James F. W. Ross, of Toronto. The scientific work of the association will begin on Tuesday morning at ten o'clock, and end Friday at one o'clock, and it is expected so to arrange the programme as to afford the members opportunity to visit the places of interest each day on the adjournment of the afternoon session. The secretary of the association is Dr. William Warren Potter, of Buffalo.

A Lost Opportunity.—The jubilee exercises proper on the third day might have been worse and there was abundant room to have made them better. The occasion afforded ample opportunity for hero worshippers to display their enthusiasm, and otherwise it was a restful break in the routine. Dr. N. S. Davis read his address in good voice and the subject matter was an interesting bit of history. The opportunity was here afforded to invite the president of the Medical Society of the State of New York to participate in the proceedings, at least by his personal presence; but it was lost, more's the pity. To ignore completely a great medical society, that was founded in 1806 and was the first organized body to give direction to medical education in the United States, in which also the American Medical Association had its birth and after which its form of government was modelled, was in our view an error, if not a misfortune. These jubilee exercises were distinct and apart from the ordinary work of the association, and during their conduct it would have been a graceful act for Dr. Davis to have welcomed the president of that society, nor would it have diminished the renown that is so justly accorded to the "father of the association" had he displayed a magnanimity that was worthy his exalted position and the occasion.—*Buffalo Medical Journal.*

The Statue of Charcot, by the sculptor Falguière, is nearly finished, and will soon be erected at the Salpêtrière.

Government Doctoring.—From Queensland comes a proposition that the principle of lodge practice be widened out so as to be made a State institution. The *Medical Press* says that the president of the local branch of the British Medical Association has made the startling suggestion that the medical care of the

people should be part of a public-health department, and it is said that a large proportion of the members of the branch was charmed with the idea. He proposes that the whole country be divided into districts, with a senior and two junior medical officers to each, together with relieving officers and inspectors. Every person is to be taxed two dollars per annum to pay for his or her doctoring. This is a distinct improvement on the dollar-a-month dispensaries and fifty-cent hospitals. It also solves the dispensary-abuse problem, by extending the benefits of pauperism to the entire community without any property qualification whatever. We regret we are unable to publish the name of the president of the Queensland branch of the British Medical Association. He is a genius.

The Passing of the Parrot.—If the parrot in his tropic home could say what he thinks, he would thank his stars for psittacosis, that form of bronchopneumonia from which his captive brethren suffer in European cages. In Genoa fourteen persons, of whom eight have died, recently contracted the disease from two parrots brought from Brazil. The alarm has spread over the continent, and the parrot is in much less request than formerly.

The Pedic Society of New York, composed of the registered chiropodists of the State, held its annual meeting in this city on July 10th. The society has one hundred and seventy-one members.

An Incredible Accusation and its Refutation.—One of the most unfortunate, uncalled-for, and disgusting spectacles which men sometimes make of themselves occurred recently in St. Louis, at the close of a three-days' session of an auspicious medical society. A so-called "smoker," one of the social features of the occasion, which had been widely advertised and to which men of prominence had been invited, degenerated from a pleasant social gathering to a most disgusting, vulgar, and vile exchange of lewd jokes and foul, reeking stories, at which even the untaught, unpractised, barbarous men of the time of Molière would blush.—*The Medical Fortnightly.*

A medical journal which claims to be a St. Louis publication, but which is printed and mailed at St. Joseph, Mo., and edited at Jacksonville, Ill., criticises the "smoker" given the Tri-State Medical Society at its recent meeting in St. Louis—probably because the leaders in the entertainment were Drs. James Moores Ball and Emory Lanphear, each generally understood to be *persona non grata* to the Jacksonville editor. The gentleman wrote the criticism upon "general principles," quite evidently, for he was not present, and none of the frightful things pictured by his heated imagination actually occurred. — *American Journal of Surgery and Gynecology.*

High Potencies Come High. — An American was taken down with pneumonia last winter in a Paris hotel, and was attended by the hotel physician. The doctor was a homœopathist and treated his patient on strictly homœopathic principles, but did not furnish the remedies. These were obtained on his prescription from a neighboring pharmacy, and the bill for those consumed in the few days of the victim's illness came to $150.

The Medical Inspectors of Schools. — The first quarterly report since the appointment of medical inspectors of schools in this city has just been made by Dr. Blauvelt, the chief medical inspector. The report includes a table showing the different kinds of diseases for which children were excluded from the schools. Parasitic diseases of the head appear to have been the most prevalent, 2,627 cases having been discovered among the children examined. Contagious diseases of the eye come next on the list, over 700 cases being reported. Skin diseases claimed 175 victims, and diphtheria 91. Measles was responsible for the exclusion from school of 51 children, and 20 cases of genuine scarlet fever were discovered. Croup was of comparatively rare occurrence, but 26 scholars were compelled to forego school attendance for a short time on account of whooping-cough. The report gives the number suffering from mumps as 117, and from chicken-pox as 93.

International Association of Railway Surgeons.—At the session in Chicago of the National Association of Railway Surgeons, out of compliment to the membership in Canada and Mexico, the name of the society was changed to the International Association of Railway Surgeons. The next meeting will be held in Toronto, in May, 1898.

Beds for Sick Americans in London.—As a memorial of the Queen's diamond jubilee the Americans residing in England have endowed a bed in perpetuity in each of the five leading London hospitals, each bed being endowed with the sum of £1,000. The beds will be especially for the use of Americans, but other patients may be received if all the Americans are well.

Mississippi Valley Medical Association.—The next meeting of this association will be held in Louisville, on October 5, 6, 7, and 8, 1897. The railroads will offer reduced rates. The president is Dr. Thomas Hunt Stucky, and the chairman of the committee of arrangements Dr. H. Horace Grant. Titles of papers should be sent to the secretary, Dr. H. W. Loeb, 3559 Olive Street, St. Louis.

Pathological Society of Philadelphia.—A stated meeting of the Pathological Society of Philadelphia was held on June 24th, Dr. Charles W. Burr occupying the chair. Dr. John M. Swan exhibited an aneurism of the aorta at the junction of the ascending with the transverse portion of the arch, together with an enormously enlarged heart. Dr. William G. Spiller exhibited microscopic preparations of giant cells of the cerebral cortex. Dr. C. W. Burr exhibited a subcortical neoplasm of the precentral lobe of the left cerebral hemisphere. During life there had been evidence of suppurative inflammation of the middle ear of the same side, and the nervous phenomena were attributed to abscess of the brain. The mastoid cells were trephined and pus was afforded exit, but no improvement in the nervous phenomena followed.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

SECTION ON ANATOMY AND SURGERY.

First Day—Tuesday, June 1st.

President's Address.—The chairman, DR. R. H. SAYRE, of New York, in his opening address, recommended that papers be fewer in number and well prepared, in order to allow more thorough discussion, which was of great importance. It was not always easy to discuss a paper on the spur of the moment. He thanked the section very heartily for the honor conferred upon him in calling him to act as its presiding officer.

Ligation of the Carotid.—"(*a*) Ligation of the Common Carotid Artery for Trifacial Neuralgia, with Experiments and Observations on Dogs. (*b*) Specimens and Charts of the Arterial and Nervous Systems Illustrating the Paper." DR. B. MERRILL RICKETTS, of Cincinnati, Ohio, read a paper with this title, in which he stated that only experimental work had been done, and that as yet but few conclusions could be drawn. The anatomy of a dog was thought to be different from that of a human being, but he did not concur in that opinion. Sir Astley Cooper ligated the vertebral and common carotid arteries in a dog, but the object of the operation was not known. In 1866 Ehrman ligated the common carotid for trifacial neuralgia. The operation had also been done by Gross in 1883, Hutchinson in 1885, and Horsley in 1887. The cases operated upon had not been reported in detail. The speaker wished to mention a case operated upon one year ago. The patient was ninety-six years of age, and since the operation he had been entirely free from pain. The question arose as to the reason for this relief. It was supposed that changes took place in the Gasserian ganglion, but the microscope proved that such was not the case. The experiments extended over three months; twelve dogs were chosen, their common carotids were ligated, and the dogs were killed at different times afterward. From these experiments he concluded that pain results from one of two conditions: first, anæmia; and second, congestion. He referred to the pain of local meningitis. In case of congestion, ligation of the common carotids will relieve the pressure and blood tension. Specimens were shown of the brains of dogs killed on different days; the injection material used was composed of starch, carbolic acid, and aniline.

DR. J. B. MURPHY, of Chicago, asked what percentage of cases of ligation showed degenerative changes in the hemispheres; he also inquired of the author what his theory was as to the pathology of trifacial neuralgia.

DR. RICKETTS, in closing the discussion, said that there were no changes in the hemispheres, so far as he was able to discover. Congestion seemed to be a prominent factor, as also did anæmia. The speaker then referred briefly to Rose's and Langenbeck's operations for the cure of trifacial neuralgia.

The Nerve Element in Surgical Pathology.—DR. J. MCFADDEN GASTON, of Atlanta, Ga., read a paper with the above title. He said that the interlacing of the nerves with the different structures of the body gives energy to every vital organ in health, and aggravates their disorder in disease.

Neuralgia in all its protean forms is not a mere functional derangement of the nerve centres, but depends in most cases upon local modifications resulting from inflammatory action in the neurilemma or parenchymatous structure of the affected nerve. It may also exist in a spurious form connected with compression upon the trunk, or from cicatricial adhesions after operations. The impression that contraction of the nerves gives rise to painful development has led to nerve stretching, but little advantage has attended this procedure, thus showing that nerve shortening is not pathognomonic.

Rheumatic complications involving various regions of the body are dependent upon the nerve supply to the part, and the acute sensibility of such structures renders anodynes of the greatest importance in the treatment of such disorders. Inflammatory processes are accompanied by pain from the entrance of sensory branches of the nerves into the organs, and the means adopted for the relief of inflammation must include the control of the neurotic disturbances by combating pain. It is fair to infer that all agencies for the mitigation of pain have a curative effect upon the structures involved in disease.

The reciprocal influence of body and mind in the progress of most physical disorders depends upon their connection through the nervous system.

Our deficient knowledge of the etiological factor involved in shock inclines the speaker to the view that a continuous baleful influence is propagated to the nerve centres from the disintegration of the structure involved, and that this may be modified by amputation with a clean incision through sound tissues above the point of injury, soon after such violence to the parts. The injury inflicted upon the superficial cutaneous nerve fibrils is extended to the internal organs by the correlation of nerves and capillaries with the viscera. The notable effects observed from cups, sinapisms, and blisters upon the skin are due to the sympathies established through this channel of the nerves. The eruption of teeth in children is attended by neurotic disturbances of a marked character. The various manifestations of the intimate relations of the nerves with the different structures of the body open the way for comprehending the rôle of the nerve element in surgical pathology.

The development of traumatic neuritis is the most common complication of surgical cases, and there is rarely any extensive lesion which is not accompanied by more or less pain, dependent upon inflammation of the nerve or its neurilemma. The irritation of the peripheral branch of a nerve may set up a train of disorders terminating in tetanus or lymphangitis, and the serious consequences of these affections are notorious. In the latter condition ganglions as well as lymphatics become involved in the inflammatory process, and suppuration is set up in the course of the lymphatics with the characteristic features of pyæmia.

The subcutaneous use of simple distilled water has been resorted to with apparent effect upon the nervous system, and this proves a delicate response of the nerves to the action of agents introduced hypodermically. The transmission of cutaneous modifications to the internal organs becomes in numerous instances simply the expression or delivery of a dynamic influence which operates through the nerves. Instead of local irritation there is a general influence upon the organism corresponding to the special property of the agent employed, and we must attribute the effect to the conduction of medicinal powers from the point of introduction through the various channels of communication with the dependent structures.

The chief features in the relations of the nervous system to other structures involved in surgery lead to the following deductions:

1st. The cutaneous development of the minute branches of the cerebro-spinal system of nerves, and the ganglionic ramifications of the great sympathetic, are so related to the capillaries as to establish a recip-

rocal action and reaction between them and the great nerve centres.

2d. The vasomotor nerves are so intimately linked with the excito-motor and excito-dynamic system of nerves that impressions made through the superficial afferent nerves are conveyed to all the corporeal structures and tissues, so as to produce their effects upon different organs.

3d. Reflex phenomena depend upon a complex interchange of local pathological conditions with the nervous ramifications to remote parts of the body.

4th. The fountainhead of energy for all the functions lies in the nerve centres, and by controlling emanations from this source the vital forces will be propagated with regularity and uniformity to all the remote parts of the physical organization. On the contrary, a hurtful influence disseminated from the nerve centres entails disease upon the different organs.

5th. The means to be adopted for averting injurious impressions upon the nerve centres, and the measures to be used for the correction of their derangement, make up the whole prophylactic agency of hygiene, and include all the therapeutic appliances in the treatment of diseases, as well as the application of surgical measures.

6th. Close observation of the various modifications of the nerve element on the physical organism should reveal its direct influence in surgical pathology, and lead the surgeon to the adoption of proper means of relief.

Operative Procedure for the Relief of Occlusion of the Jaws.—Dr. J. Ewing Mears, of Philadelphia, read a paper on this subject. With regard to the procedures which have been used, Mr. Heath, of London, in recording a case in which he had operated, made the statement that English text-books contain very little. Drs. Kocher and Valentine Mott both refer to a case of a sloughing cheek which was accompanied by closure of the jaws. The most complete account of this condition is to be found in Gross' "Surgery." This surgeon had opportunity to study cases in the Southern section of this country, where this condition is more often found. He recognizes two forms —the temporary or spasmodic, and the permanent. Among the many causes of the temporary or spasmodic form, the speaker mentioned delayed eruption of the molars, alveolar abscess in connection with the teeth, and tonsillitis. The treatment of this form depends entirely upon the cause. If it is due to a wisdom tooth, the tooth should be extracted. In regard to the permanent form, this is due to cicatricial tissue or to osseous bands which result from the use of mercury. The speaker here showed a cast illustrating the absence of development of the lower jaw. Closure of the jaws may result from inflammation, which is more often rheumatic in character. It may result from blows or concussions, but is most frequently due to an unrecognized fracture involving the neck of the condyle. The diagnosis of these cases may offer great difficulties. A complete history should be obtained. If a deviation of the lower jaw to the affected side exists, it will aid the diagnosis. The prognosis is favorable. In considering the treatment the speaker stated that cicatricial-tissue deposits tax the skill of the surgeon. Different operations for forming false joints have been advocated. The speaker then briefly described his method of treating these cases. A long curved needle, armed with strong silk, is introduced in such a way that the silk encircles the cicatrix. The ligature is then drawn backward and forward day by day, and thus inflammation is set up. The jaws are separated and a gag is placed between the teeth. The use of the gag is kept up until the patient is able to open the jaw without it. The speaker then showed photographs of patients operated upon.

Dr. McLain, of Detroit, said that the subject of jaw closure was very interesting and important, especially because of its rarity. He had had some experience with this trouble. He thought it was difficult to imagine anything more annoying than an ankylosis of the jaw. He referred particularly to the ankylosis following scarlet fever, that being a frequent cause, in his opinion. He related the brief history of the case of a patient who was entirely unable to move the jaw There was absolute ankylosis on both sides. He tried to relieve the condition by what he thought to be an original operation. He dissected off part of the muscles of the jaw at the angle, and resected a V-shaped piece from each side; he kept up passive movements until false joints were formed on both sides.

Dr. Lewis A. Sayre, of New York, hoped that Dr. Mears would speak of the operation first described by Dr. Schmidt, of New York, which consisted in prying open the jaw and constant use of the joint.

The Chairman thought that each case must be dealt with according to its merits. Bony ankylosis must be treated on different lines. He related the case of a patient, six years of age, who had ankylosis of the jaw for several years before his parents noticed any trouble. Treatment consisted in prying apart the jaws by means of a strong wedge, which was covered with lead to engage the teeth.

Improvement of Brain Function by Surgical Interference.—Dr. Ernest Laplace, of Philadelphia, read a paper with this title. Sepsis has practically been eliminated from brain surgery. Relief depends upon ability to remove the transient cause, which is either chemical, psychical, biological, or mechanical. He thought too much importance had been placed upon the purely functional troubles of the brain. In brain surgery the technique must be perfect. We should guard against shock, hemorrhage, and sepsis. Death from shock is due usually to faulty technique. The treatment of this condition should be by strychnine hypodermically, hot-water bottles, head in the dependent position, high enemata of hot water, etc. The most frequent indication for operation is concussion following trauma. The sequelæ dreaded are insanity or epilepsy. If consciousness is lost we must relieve this condition by blood-letting, thus reducing the tension of the parts and also swelling, which may exert pressure. The latter condition Dr. Laplace relieves by transverse craniectomy, beginning the operation in the temporal fossa and going through the thick portion of the skull. One sometimes finds the middle meningeal artery running through the skull and not through a groove. He showed an instrument which he uses to separate the adhesions under the skull, especially over the longitudinal sinus. This instrument is no larger than an ordinary wire, and as it advances does not tear the dura. The knife is then plunged through the surface of the dura; the brain tissue bulges through this opening, but not enough to do harm. Then he proceeds to pack the wound with gauze fresh from the sterilizer. For purposes of packing the speaker said he did not favor iodoform or other gauzes, but only gauze taken directly from the sterilizer after it has been subjected to a heat of 230° to 260° F. He packs this well into the groove he makes, and this gives support to the brain. The strip is left eight days *in situ*, and then removed. In this operation there is no shock or loss of blood, and there is no vibration through the brain. He reported twenty-two cases treated after this method with good results. In acute meningitis this method of drainage has been applied with advantage. Fifteen epileptic patients operated upon gave evidence of improved mental condition, and in no case was the patient worse after operation. In idiocy due to microcephalus—operation at the coronal, sagittal, and frontal sutures, done at three months' intervals—some cases showed marked improvement both physically and men-

tally, and here again no case was worse after operation. The speaker then referred briefly to a class of cases of arrested development of the brain, in which this operation had been performed. In a few cases the mental condition was certainly improved.

Demonstration on the Cadaver of a New Surgical Engine.—Dr. M. H. Cryer, of Philadelphia, read a paper on this subject. He exhibited a modified dental engine, which differs from the ordinary dental engine in that it is much more powerful and can make more revolutions to the minute. He laid particular stress on the fact that the parts are detachable and can be made aseptic, and that the instrument can be used in all bone operations. Another advantage that it possesses is that it will not cut the flesh unless the flesh comes between the bone and the burr. The speaker then demonstrated the use of his new surgical engine on the head of a cadaver.

Dr. Wyman, of Detroit, believed that the ideas of Dr. Laplace were with us to stay. Without drainage the majority of cases terminated in death. All cases were improved by surgical interference. In regard to the apparatus shown, he asked how it worked in the living subject. Bloody fluid, bone dust, etc., choked up the burrs of the saw now in use, and he asked how this new machine stood the test. He had long wished for some such instrument.

Dr. De Velbris, of Toledo, spoke in regard to the removal of the skull bone, as demonstrated by Dr. Cryer. He thought the instrument worked admirably. The great difficulty that he had experienced in instruments that he had used was that he could not cut a circular slit.

Dr. White, of Philadelphia, said that he was not so fortunate in his cases as was Dr. Laplace. He was of the opinion that the mortality of all operations of opening the cranium was considerably above two per cent. He did not believe that the whole brain could be drained through an opening in the dura mater. The temporary effect of an operation should be considered. He reported cases in which operation had been performed for epilepsy. Some cases apparently gave something to guide in operation, but when the part was cut down upon nothing was found. Occasionally the opening of the cranial cavity was followed by the disappearance of the so-called organic disease; it was not understood why this was so. The speaker thought that in insanity following trauma operation was rational and justifiable.

Dr. Lewis A. Sayre, of New York, spoke of the spiral conical trephine. One could not possibly injure the dura mater with this instrument, and he was surprised that this fact had not been mentioned. The speaker related a case in which convulsions and other symptoms led him to believe that an exostosis was pressing upon the brain. An operation was performed, but nothing was found. Since the operation, which was done many years ago, the patient had not had a convulsion and was perfectly well.

Hernia of the Cæcum.—Dr. J. H. Gibbon, of Philadelphia, read a paper with this title. He spoke of acute and chronic partial intestinal-wall herniæ, giving the theory of the manner of their production, symptoms, diagnosis, and treatment. The usual symptoms of acute hernia might be present—inflammation, gangrene, and perforation. Littré's hernia was a hernia of Meckel's diverticulum. The object of the paper was to prove that acute partial intestinal-wall hernia does occur, and also that acute partial enterocele must be differentiated.

Second Day—Wednesday, June 2d.

Two Hundred and Fifty Bassini Operations for the Cure of Hernia, without Mortality.—Dr. W. B. De Garmo, of New York, read a paper with the above title, it being largely one of statistics of his own cases. Two hundred and fifty operations had been done on 216 patients; 34 operations had been done on both sides. There were 164 males and 86 females; 55 were under the age of fourteen years, 43 between the ages of fourteen and twenty-five, and 118 had passed the age of twenty-five years; 8 were between the ages of sixty and seventy, and 2 were over eighty. The youngest patient was five months old and was operated upon for strangulated scrotal hernia; he recovered in ten days. The oldest patients got well apparently as readily as the youngest. There were 93 scrotal hernias, 55 irreducible, and 16 strangulated. The largest hernia was about two feet in circumference, composed of large and small intestines, omentum, and bladder. In 4 cases cysts were found in the canal; in 1 case it was a form of multiple cyst; 207 cases healed by primary union. Suppurative cases started beneath the skin in all cases, and one was from gonorrhœal infection. In only one instance did a recurrence take place in a suppurative case. All double operations were done at the same time. In one case there was a direct inguinal hernia on the left side and a femoral hernia on the right side; both were operated upon at the same time. In regard to suture material, he used none but kangaroo tendon. He had had no deaths. The permanence of cure was a very important thing to consider. He thought that ninety per cent. of permanent cures was too low, and advanced his percentage to ninety-five. One hundred and fifty of his cases had gone over one year without recurrences. He had had only three actual recurrences up to the present time. The real cause of failure was known in every case and was reported by the speaker.

Dr. Marcy, of Boston, in opening the discussion, thought the subject too large to be treated in detail, but wished to speak of one or two points which he considered to be essential. He demonstrated by drawings on the blackboard the causes of hernia. He asked why all were not subjects of hernia; the opening in the abdominal wall was at right angles to the abdominal pressure. He pointed out that anatomical defects caused a large proportion of the cases, such as pathological conditions and lack of closure at an early period of life. In treating these cases, questions arise as to the reconstruction of these parts. The speaker then briefly related a history of his researches and publications on this subject. He had operated upon subjects of three months and upon those past eighty years of age. In making up the mortality list he did not think that strangulated cases should be included in the percentage; ninety per cent. had remained cured. He used no truss after operation. The young should be operated upon as well as the older subjects. All persons in the category of truss-bearing subjects are susceptible of certain cure.

Dr. Ochsner, of Chicago, wished to discuss the age limit. It was apparent to all those who saw many cases of hernia that they did well with a truss until they got an enlarged prostate, when difficulty began. He had done castration and ligature and section of the cord on the side of hernia. As a result urination was made easy and the trouble disappeared. The increased pressure on the hernial ring was diminished. This was a principle worthy of consideration. He had seen several hundred children suffering from hernia, and had found that in many cases these children had a phimosis, and as a consequence strained during urination. Circumcision, followed by placing the patient in bed with feet elevated to an angle of forty-five degrees for four or five or six weeks, would result in a cure. He did not think it justifiable to operate in children under twelve years of age. His experience

had been that practically all children recovered without operation.

Dr. Ricketts, of Cincinnati, asked in reference to dealing with the testicle, if any operator had met with a hydrocele accompanying an undescended testicle.

Dr. De Garmo closed the discussion. He stated that to Marcy, of Boston, and not to Bassini, should the credit of the so-called Bassini method be given; that Marcy was the first to attempt to restore the canal to its normal condition. None of the cases Dr. De Garmo operated upon had enlarged prostate. Phimosis he had studied, and had arrived at the conclusion that few children had phimosis so marked that they strain to force urine through the urethra. Examination of children in Hebrew institutions showed that just as many hernias occurred there as elsewhere. He certainly did not believe in elevating the bed, as advised by Dr. Ochsner, but preferred to operate. In regard to hydrocele occurring with an undescended testicle, he had seen one case, in which the tumor was as large as a hen's egg. In two cases of undescended testicle the cord was so short that he could not bring it down. If the cord was long enough, he believed it was best to bring down the testicle. He looked upon the aponeurosis of the external oblique muscle as tendon, and in his operations for hernia treated it as such. He was perfectly satisfied with kangaroo tendon.

Treatment of Abscess of the Lung.—Dr. Carl Beck, of New York, read a paper with this title. Abscess of the lung is not a rare condition. Its attempted cure should be by purely surgical principles. The diagnosis is much easier than its localization. The absence of tuberculous manifestations and exploratory puncture point to this condition. The principles of treatment consist of thorough evacuation of the pus and drainage. Particular care should be employed in rendering the skin aseptic, twenty-four hours being devoted to this purpose. The speaker then described the operation for entering the pleural cavity. If no adhesions exist the lung may collapse. Palpation of the lung area and the introduction of the needle into the lung may locate the pus focus. The Paquelin cautery thrust into the suspected portion is a useful aid in diagnosis; then one should introduce a director and watch for the pus. After the cavity is exposed, no irrigation is necessary. Iodoform gauze should be packed into the cavity. The speaker advised blowing with the mouth frequently to increase the discharge. After the operation small doses of morphine may be given. At the end of a week strophanthus and caffeine are advised. Anæsthesia should be given only when the patient is able to stand it. Even cocaine has its dangers. His experience was obtained from four cases, all of which terminated in recovery. In only one of these cases was the diagnosis of lung abscess made before operating. The history of this one case was given in detail.

Dr. Manley, of New York, said that purulent formations were often difficult to deal with, and it would seem to him that in empyema it was a difficult matter to determine whether it was due to a transformation of a serous fluid or whether it was an interstitial abscess. He believed that it was impossible to decide whether it would be better to trust to the exploratory needle or to aspiration. He asked Dr. Beck if, in the case of a child, it would not be better to spare the ribs as much as possible.

Dr. Beck said that if pus was present the ribs should usually be resected, and then one could readily find a way to the pus cavity. He advised the employment of the *x*-ray in all cases of resection of the rib.

The Diagnosis of Minor Personal Injuries and their Relation to Accident and Insurance Associations (with Illustrations).—Dr. Liston H. Montgomery, of Chicago, Ill., read a paper on the above subject, in which he called attention to declarations made by policy holders which were followed by unwarranted legal proceedings. He reported several cases showing what basis claimants had for demanding damages. He referred to the decisions of courts in regard to certain injuries and the possible errors of judgment which may occur. He brought up the question of the liabilities of companies in septic infection.

Anchoring the Kidney.—Dr. R. Harvey Reed, of Columbus, Ohio, read a paper on this subject. He stated that hydronephrosis and pyonephrosis are of frequent occurrence, due often to closure of the ureters from a calculus or other obstruction which prevents the flow of urine. Hydronephrosis may exist for from ten to fifteen days without breaking down the substance of the kidney. A kidney absent from its natural position, may be replaced sometimes by taxis, but it is liable to return to its former position. When this does occur we are justified in doing a radical operation. The speaker then showed by diagram the futility of attempting to replace a kidney in its natural position and hold it there by means of a tight bandage. The bandage could not be made tight enough to effect this object without interfering with the circulation; one could get only general and not local pressure by this means. He called attention to the objections made to the radical cure of floating kidney and showed pictures illustrating his method of anchoring. He uses the abdominal incision over the normal position of the kidney. The incision is made just large enough to introduce the fingers into the cavity and push the intestines to one side, so as to give a clear field for observation. A long curved needle with a strong handle, and armed with one thread of silk, kangaroo tendon, or other material, is passed through the upper border of the kidney between the eleventh and twelfth ribs and on through the muscular wall out to the back. The needle is unthreaded and withdrawn. The other end is threaded and introduced at a short distance from the point traversed by the first; the threads are then tied over a piece of gauze in a manner similar to the fastening of a staple stitch. The speaker thought that in going in through the lumbar region one would experience greater difficulty in introducing the needle. This was a radical operation rather than a palliative one. The sutures were left in for from ten to fourteen days. In two instances it was his good fortune to be called upon to operate for ovarian trouble in patients on whom he had once performed this operation. One of these operations was performed at an interval of six months after the first operation, and the other at an interval of one and a half years. In both instances he found the kidney in the normal position, the same as the one on the other side. The speaker thought there were objections to the lumbar incision. One does not always find the kidney where it ought to be and is sometimes compelled to hunt for it. By the abdominal route a greater field for observation is obtained.

The Comparative Merits of Different Operations for Stone in the Bladder.—Dr. J. B. Deaver, of Philadelphia, read a paper with this title, in which he said there are two operations which are quite popular: first, suprapubic lithotomy, and second, litholapaxy. Litholapaxy is applicable in nearly all cases of stone. The most important condition which would interfere with this operation is stricture in the anterior or deep urethra; still, with Otis' urethrotome, this difficulty can be obviated. Stricture of small calibre in the deep urethra is no contraindication for the operation of litholapaxy, but if the deep urethra cannot be restored the operation is then out of the question. If the stone is large, perineal lithot-

omy is the operation. In speaking of enlargement of the prostate gland, the reader of the paper said that no enlightened surgeon of the present day would recommend castration. Cystitis is not a contraindication in litholapaxy; it is essentially present in stone in the bladder. Almost all senile cases improve under litholapaxy, and this operation does not seem to aggravate the condition of senile cystitis. When the stone is large, litholapaxy is difficult, because to crush a large stone one must use a large lithotrite. In these cases it is better to do a suprapubic lithotomy. Experience is the factor which must decide the operation. For success in this operation it is essential that it be done at one sitting. A large stone with an irritable bladder makes litholapaxy inadvisable. If one is not skilful in manipulation, one had better do the cutting operation. Sometimes the stone is so large as to necessitate a cutting operation. In case of an encysted stone one should not perform a litholapaxy. If the pelvis of the kidney is diseased, the gravity of the operation is increased. Litholopaxy is by far the safer operation, as statistics show. Cutting operations must be made whenever indicated. As regards children under thirteen years of age, this operation should not be done on account of the high mortality, and again the urethra is rarely so large as to permit the passage of an instrument; cystitis is frequently set up by the operation. A great advantage of litholapaxy is that the patient can resume work after ten or fifteen days. In operating upon a child one should bear in mind that the first two inches is the smallest portion of the urethra. The speaker advised the use of a lithotrite which does not become clogged; a fenestrated lithotrite is the better instrument. Suprapubic lithotomy is the operation that should be done by those who deal with stone in the bladder but occasionally. For old men, in whom stone is associated usually with enlarged prostate, suprapubic lithotomy is the operation. One should remember that in pelvic deformities, ankylosis of the hip-joint, etc., one may not be able to place the patient in the lithotomy position. The great advantage in the operation of litholapaxy is that it lessens the sojourn in bed, and the sequelæ of cutting operations are not present.

Demonstration of the Technique of the Roentgen Rays with the Practical Application to Surgery, Illustrated by Stereopticon Views.—Drs. De Forrest Willard and A. W. Goodspeed, of Philadelphia, presented a paper on this subject.

Dr. Goodspeed demonstrated to the section the technique of the Roentgen rays.

Dr. De Forrest Willard exhibited upon the screen a number of skiagraphs taken for him by Professor Goodspeed, illustrating the advantages of this process in fractures of the bone, especially those in the neighborhood of the joints, as regards both diagnosis and treatment, the process being especially valuable when the displacement is concealed by excessive swelling. In regard to deformities following fractures and cases of non-union, he warned surgeons against placing too much faith in delineation; it should be employed only as an adjuvant to existing clinical symptoms. Errors are possible, as has been demonstrated by various practical workers. The benefit of the skiagraph in diseases of bones, tuberculous joints, ankylosis, exostosis, etc., is beyond question. In distortion of the bones, knockknees, bowlegs, etc., it is useful. Foreign bodies in the superficial tissues, œsophagus, chest, abdomen, and even pelvis are often easily demonstrable, but the exact location and depth cannot be accurately disclosed except by various processes of angulation, marking, etc. The fluoroscope is very helpful. The wandering habit of needles makes their location a matter of considerable difficulty. Localization of gall stones, stones in the bladder, stones in the kidney, etc., while still somewhat difficult, is a matter that will be easily accomplished as the method and technique of the process advance month by month. Many interesting radiographs were shown by Dr. Willard.

Third Day—Thursday, June 3d.

Some Additional Facts Relating to Skin Grafting, Technique, etc.—Dr. Z. J. Lusk, of Warsaw, N. Y., opened the day's proceedings with a paper on this subject. He referred briefly to his own experiments and writings, and the results he had obtained, relating in detail five cases. He emphasized the fact that great care must be taken in separating the cuticle, and that it should be kept free from moisture. He obtained his cuticle from blisters produced by heat.

Dr. George M. Sternberg, of Washington, D. C., thought it remarkable that a temperature high enough to raise a blister did not destroy the cuticle. He thought that experiments should be made to find at what temperature the cuticle is destroyed. He would advise that some such experiments be instituted.

The Chairman said that he had been surprised to note the resistance of the living tissues to dry hot air. He had used this treatment in chronic arthritis, and exposed joints to a very high degree of heat. Skin will endure from 350° to 400° F., which he had thought hardly possible. Some can stand not more than 180° or 220° F., but many can stand much higher than 400° F. He had noticed that after a few days had elapsed ulcerated spots, etc., sometimes appeared, which ulceration was difficult to heal.

Dr. Manley, of New York, said that Dr. Lusk's plan was not true skin grafting, but was epidermal grafting. He could not recommend this manner of grafting in the class of cases described by Guermonprez, in which he covers in a large surface, as of the whole limb. He thought Thiersch's method a very good one. When extensive destruction had not been done, he thought the reader's plan a very good one, especially when motion was not great.

The Traumatic Fevers.—Dr. E. W. Holmes, of Philadelphia, read a paper on the above subject. He classified traumatic fevers into:

(*a*) Primary fever.

(*b*) Secondary fever: 1, Suppurative fever—acute, chronic; 2, true septicæmia; 3, sapræmia; 4, pyæmia.

(*a*) Primary fever: Primary or aseptic fibrin-ferment fever appears usually within forty-eight hours after a traumatism of any magnitude, being due to the absorption of an aseptic fibrin-ferment substance from the seat of injury. It follows conditions in which the aseptic precautions or unbroken skin preclude infection, and is due to the absorption of pyretogenic substances formed from the products of the aseptic microbiosis.

(*b*) Secondary fever: Secondary fever, which comes on after the fifth day, is due to the absorption of pathogenic germs, either the pyogenic, the saprophytic, or their products. Under secondary fever he considered:

1. Suppurative fever, which may be acute or chronic.

Acute suppurative fever follows infection with the products of pyogenic micro-organisms, and is manifested by chill, fever, and sweat, usually coincident with the formation of pus. These symptoms usually disappear when the pus is thoroughly evacuated and the cavity drained. Acute suppurative fever is believed to be due to the products of the pus and not to the actual presence of the pus organisms themselves: (1) because the actual presence of the pus germs has not been demonstrated in the blood; (2) because the symptoms disappear so quickly after thorough cleansing and drainage.

The chronic form of suppurative fever, with characteristic rhythmic temperature chart, "up at night and down in the morning," with flush of cheek and wasting of flesh, is called hectic.

2. Septicæmia (true septicæmia, septic infection) is due to the absorption of the saprophytic germs or micro-organisms of putrefaction, with their actual presence in the blood in enormous quantities. The symptoms are an initial chill (one only), a continued fever, rapid pulse and respiration, coma, sordes on the lips, a dry cracked tongue, mental hebetude, muttering delirium, with enlargement of the spleen and of the superficial lymph glands. The wound, if upon the surface, will often appear gangrenous and emit a foul odor. Treatment consists in rigid local asepsis and the most vigorous supportive measures.

3. Sapræmia (toxæmia, septic intoxication, ptomain poisoning) is due to the absorption of the products of micro-organisms (ptomains) from the seat of infection. It is evident that while true septicæmia emphasizes the actual presence of bacteria in the blood itself, sapræmia depends largely upon their limitation to the point of introduction and the destruction of tissue there, and is due to the absorption of the products from the original point of infection. Sapræmia is often ushered in with a single chill, followed by fever and sweat, tenderness and pain at the infected spot, or, if the wound be under observation, it will appear swollen, with inflamed edge and covered by unhealthy granulations. The skin is hot, the pulse and respiration are rapid, the tongue is dry and thickly coated, the urine scanty and highly colored; the patient is restless, with a mild delirium. This condition lasts four or five days, and the symptoms gradually subside. It is in obstetric practice that this form of disease is too often found. The whole course of sapræmia emphasizes the local element, and to local treatment we must look for its removal. The constitutional treatment consists of stimulating and supportive measures.

4. Pyæmia: Few terms in surgery are so confusing as pyæmia. It seemed to the speaker that we can safely restrict the term to a distinct disease characterized by a state of depression common to all typhoidal conditions, but distinguished by the formation of pus cavities in different and widely separated parts of the body. No tissue can be exempt. There is here surely a double infection, the micro-organisms of putrefaction and of pus both being introduced directly into the blood, and the latter proliferating wherever they happen to lodge. The symptoms appear about the second week after the injury. They are repeated chills and colliquative sweats, the temperature rising synchronously with the chill, the pulse and respiration rapid and weak, with icteroid skin, anorexia, more or less diarrhœa, great prostration, great pain at the immediate seat of the abscess, hyperæsthesia of the cutaneous surface, and erythematous rashes and ecchymoses; the mind is clear, unless metastatic abscesses lodge in the brain. We can differentiate it from true septicæmia by the mental clearness, the hyperæsthesia, the repeated chill (half a dozen a day) and excessive exhausting sweat, and the localized abscess. The treatment is supporting and stimulant, with early evacuation of the abscesses where accessible.

Arterial pyæmia, so-called, is an entirely different condition, being non-infective, depending upon the lodgement of an embolus in some distant organ, detached from a fibrinous white thrombus in the left ventricle. The term should be abandoned.

Cicatricial Stenosis and Valve Formation as a Cause of Pyloric Obstruction, with a Report of Five Cases Relieved by Operation.—Dr. W. J. Mayo, of Rochester, Minn., read a paper on this subject. Non-malignant forms of pyloric obstruction are not infrequent, and have been confused with cancerous disease; the subjects have usually been left to die without surgical intervention. Stricture of the pylorus following upon the healing of gastric ulcer is the most common form of non-malignant obstruction, and four out of five cases upon which the speaker has operated have been of this variety. The production of valve formation at the pylorus is similar to the valve formation of the ureter at the pelvis of the kidney as a cause of hydronephrosis and pyonephrosis, so graphically portrayed by Fenger. Enteroptosis favors such obstruction. A few cases of congenital stricture have been reported. The diagnosis of marked pyloric obstruction and the consequent dilatation of the stomach are not difficult. The gastroscope and the gastrodiaphanoscope are of little practical value to the surgeon. The differentiation between malignant and non-malignant forms of obstruction is often difficult, and may be impossible without exploratory incision. Examination of the stomach contents is of value. When the meal test of Ewald and Boas shows the absence of free hydrochloric acid with Günsburg's test, and at the same time develops lactic acid by Uffelmann's method, the indications are for cancer. After all, the chief factors in the differential diagnosis will be obtained from a careful examination in connection with the personal history of the patient. He called attention to the significance of enlarged glands in the greater and lesser omenta as evidences of malignancy. Bull states that fifty per cent. of pyloric cancer cases prove fatal before glandular infection takes place.

Operation: The median abdominal incision, between the ensiform cartilage and the umbilicus, has proved to him the most satisfactory. Pyloroplasty is the operation of choice. The incision should be in healthy tissue rather than in scar tissue, as the latter is stiff and does not nicely coapt, and atrophy necrosis often results from suture pressure. Out of five cases he was able to do pyloroplasty in but two. Pylorectomy will be seldom done for non-malignant stricture.

Gastro-enterostomy for non-malignant disease is an operation of expediency and not of choice. Extensive contractures of the pylorus, the presence of tissue unsuitable for the security of suture union, and inaccessibility of the field of operation by reason of the presence of dense adhesions to important structures, indicate its use. Taking all facts into consideration, he believes the suture method of Wölfler offers the fewest objections.

The speaker then gave a detailed history of his five cases.

The Present Status of the Injection Treatment of Hemorrhoids.—Dr. L. H. Adler, Jr., of Philadelphia, reviewed briefly the injection treatment of hemorrhoids, quoting largely from Agnew's work on surgery.

Transperitoneal Ligation of the Iliac Artery, with Report of Cases.—Dr. T. S. K. Morton, of Philadelphia, made a report on twenty-eight cases operated upon, of which number twenty-one ended in recovery. Deaths that occurred were due to abdominal complications.

The Etiology and Classification of Tumors.—Dr. S. H. Friend, of Milwaukee, Wis., read a deeply scientific paper on this subject.

Serum Therapy in Acute Surgical Infectious Diseases.—Dr. Howard Lilienthal, of New York, read a paper on this subject.

The Differential Diagnosis of Surgical Lesions in the Right Half of the Abdomen and Pelvis, with Especial Reference to the Diagnosis of Appendicitis.—Dr. George Ryerson Fowler, of Brooklyn, N. Y., read a paper on the above subject. There can be no

question that the inflammatory conditions of the vermiform appendix constitute the most important surgical lesions of the abdominal cavity in both sexes. The difficulties of diagnosis are greatly increased in the female, owing to errors arising from the presence of neighboring organs that take on suppurative inflammation. All conditions which may be mistaken for appendicitis in the male, with the sole and rare exception of an inflamed right undescended testicle, occur likewise in the female. Some occur with greater frequency in women; such are cholelithiasis and impaction of gall stones and resulting dropsy and empyema of the gall bladder, etc. Gall stones occur nearly five and floating kidney six times more often in women than in men. One should bear in mind that the right kidney is affected four times as frequently as the left. Appendical affections rank first in importance among the surgical affections of the abdominal and pelvic cavities.

Appendicitis clinically is divided into acute, subacute, and chronic. The speaker then briefly called attention to the principal points to be borne in mind in the objective and subjective symptoms of these clinical forms.

In acute appendicitis points to be noted are: (*a*) Sudden onset; (*b*) colicky or cramping abdominal pains, which in the majority of cases are referred to the region immediately above the umbilicus, and later become diffused; (*c*) vomiting; (*d*) localized pain and tenderness—this is finally referred to the right iliac region; (*e*) rigidity of the right rectus muscle at its lower part; (*f*) the presence of a tumor in the ileo-cæcal region, which makes its appearance after the first or second day; (*g*) fever, which is not marked at the commencement, and some acceleration of the pulse. Variations from the usual and typical characteristics of an acute attack consist in: 1st. Occurrence of primary general abdominal pain, rather than the localized pain. 2d. Absence of vomiting, due to the fact that the stomach is quite free from ingesta. 3d. Localized pain usually abated and right iliac tenderness diminished by the administration of opiates. 4th. Opiates may so modify respiratory movements as to render rigidity of the right rectus muscle of no service in diagnosis. 5th. Tumor is not usually to be found until after twenty-four hours; it is often delayed until after forty-eight hours. The speaker referred to the various positions in which the tumor may be found. 6th. The pulse rate may be but slightly affected in the beginning, and during an exceptionally mild attack ulcerative perforation of the organ may occur at any time with no rise of temperature.

In subacute appendicitis the onset is less stormy, and the affection is often regarded as indigestion or intestinal colic. Tenderness at the site of the appendix can generally be elicited, but usually there is no tumor. These cases, if permitted to continue, will certainly eventuate in an acute attack.

Chronic appendicitis may be chronic from the beginning. In the vast majority of cases it either eventuates from repeated subacute attacks or follows a well-defined acute attack. The characteristic clinical picture is marked by tenderness in the ileo-cæcal region, with or without the presence of tumor.

The differential diagnosis will be between lesions of gall-bladder origin, those originating in the intestine and not of necessity involving the appendix, and tubo-ovarian disease. The passage of a stone along the ductus communis choledochus may simulate the commencement of an acute appendicitis. A gall stone impacted in the cystic duct and followed by dropsy of the gall bladder may give rise to some of the symptoms of chronic appendicitis.

An acute obstruction or a perforation of the bowel in the ileo-cæcal region must be differentiated. Of less importance are the chronic obstructions and neoplasms, because they do not require such prompt diagnosis and celerity of action as do cases of acute appendicitis.

The following points should be borne in mind: Frequency—males, eighty per cent.; females, twenty per cent. History of an attack is usually that of an acute onset. Pain is usually acute and radiating. In subacute and chronic appendicitis the pain may be dull and localized. Vomiting is exceedingly common in appendicitis. Tenderness in the great majority of cases is located over the site of the appendix. Chill or rigor is of infrequent occurrence in appendicitis. Fever is present in appendicitis, although its grade does not indicate the severity of the attack. Muscular tension is almost invariably absent in adnexa lesions. Tumor is rarely present before the third day in appendicitis. It is rare that a tumor of appendical origin can be felt by the vaginal touch. The course is usually an acute one, while lesions of the adnexa are usually subacute or chronic.

The speaker called attention to the fact that one should remember that great difficulties may present themselves in establishing a diagnosis of appendicitis in the male sex under circumstances of a long appendix passing deeply into the lesser pelvis.

Fourth Day—Friday, June 4, 1897.

(*a*) **The Treatment of Colles' Fracture; (*b*) The Passing of Plaster.**—Dr. E. A. Tracy, of Boston, Mass., discussed the above subject. In 1814 Colles published his observations; previous to this time he had reported a case of this condition under the belief that it was a dislocation. The nearness to the wrist-joint and the absence of characteristic signs of fracture served to make the diagnosis of fracture difficult. The speaker then quoted the views of eminent surgeons in reference to the treatment of Colles' fracture. The views of Sir Astley Cooper, John H. Packer, Swinburne, Bright, McClellan, Agnew, and others were mentioned. The stiffness of the wrist and fingers is due to a fibrinous exudate about the tendon sheaths. The writer believes that passive motion should be employed about the fifth day. Fracture, if reduced, has no tendency to separate. The hand is placed in the semiprone position, and a splint applied which needs only moulding and no padding. In the treatment of Colles' fracture we must, first, reduce; second, protect; and third, employ passive motion of the fingers from the first day, and of the wrist from the fifth day. Dr. Manley some time ago stated that plaster of Paris is doomed. The speaker thought that plaster of Paris will be soon relegated to its proper position. Plaster of Paris is dangerous, and sometimes deadly. It does not immobilize the inclosed parts. Passive motion is important in the treatment of these fractures, and immobilization is not indicated. Splints should be applied daily and removed daily, so that the surgeon may know the condition of the fracture. He related a case of fracture which was put up in plaster-of Paris splint; after the removal of the splint, the parts were bathed in pus and the bone protruded. He wished to call the attention of the section to the wood-fibre splint, specimens of which were shown. A few facts relative to wood fibre were then given. This material can be applied to a fracture of any limb. No cotton batting is used. It is simply retained by a bandage. Swelling does not interfere with the keeping of the wood fibre in position. The splint can be readily removed, in order to conduct passive motion. He emphasized the fact that passive motion of joints should be employed at the earliest possible time. The material is porous, light in weight, clean, and can be used for months. Wood-fibre material permits of the intro-

duction of antisepsis. It is also pervious to the *x*-rays. Mastery comes to any one who possesses ordinary mechanical skill.

Dr. McFarland, of Pittsburg, said that he thought great ability was necessary in applying the splint. He could not coincide with the reader of the paper in reference to the baneful influence of plaster of Paris. He laid great stress on the use of the cotton batting. In compound fractures it is possible by the use of the fenestra to do good work with plaster of Paris. One should become accustomed to its use. Plaster of Paris does not interfere with the *x*-rays. It is now a well-recognized procedure to treat fractures by the ambulatory method—secure the limb in plaster of Paris and allow the patient to walk about—and so permit a business man to attend to his duties.

The Chairman thought that a great deal of blame had been unjustly placed upon plaster of Paris by the reader. In the instance reported by the reader of the paper, in which the plaster was said to have caused sloughing of a limb, he thought the fault was with the surgeon who applied the plaster rather than with the plaster itself; it was lack of intelligence in applying the plaster that caused the slough. Plaster of Paris did immobilize a limb if placed on properly. He thought the objection to the splint shown was the lack of good application.

Dr. Gaston, of Atlanta, Ga., said that in the restoration of bone we must have inflammatory action. If there is no inflammatory action bone does not grow together well. He has had to grind ends of bone together in order to get enough inflammatory action, and he then reapplied the plaster of Paris. He has used pasteboard splints with good results.

Dr. Fowler, of Brooklyn, stated that three-fourths of all malpractice suits against practitioners were brought about by the bad results following fracture treatment. He had used plaster-of-Paris material at one stage, and pasteboard at another stage. Wolff, of Berlin, attempted to make a spinal jacket of silicate of sodium and plaster of Paris in the same splint. This device could be applied to both extremities. The silicate of sodium was used first, then dry muslin, and lastly the plaster of Paris was applied. Later the plaster of Paris was cut away and the silicate of sodium was left. This was particularly useful for weak women, with whom the light silicate could be used instead of the heavy plaster.

Dr. Tracy closed the discussion. He stated that he had used wood-fibre splints in his practice for many years. He also stated that he now used more than ever plaster of Paris and other material. He had seen bad results follow the use of wood fibre as well as that of plaster. He agreed with the chairman that the fault was more with the surgeon than with the dressing.

Officers. — The following officers were elected: *Chairman*, Dr. W. Rodman, of Louisville, Ky.: *Secretary*, Dr. H. O. Walker, of Detroit, Mich.

Appendicitis and Typhlitis.—Dr. Storch (*Journal of Practical Medicine*, April) concludes as follows: 1. The term typhlitis as applied to diseases in the region of the iliac fossa is erroneous, misleading, and dangerous. 2. An active cathartic assisted by enemas will most always dispel all doubts as to whether we have to deal with a case of strangulation of the bowels or with appendicitis. 3. Foreign bodies are not always the sole cause of appendicitis. 4. The pathogenic intestinal microbes are pus producers and sole agents of ulceration and perforation, and as such play the active rôle in appendicitis. 5. Surgical interference at an early period is the only rational safe procedure in appendicitis.

Surgical Suggestions.

Resection of Lung.—Resection of lung, or pneumectomy, would appear at first glance to be a rational method of procedure in tuberculosis of the pulmonary structure. Surgeons who are accustomed to practise resections of the articular extremities in tuberculous osteoarthritis and extirpation of the synovia in tuberculous synovitis, and who have witnessed the gratifying results following these operations, are at once impressed with a desire to institute radical operative methods in a disease which counts its victims by thousands yearly. The pulmonary structure, however, differs from all other structures in the body in its susceptibility to infection by means of the bacillus tuberculosis, and its anatomical peculiarities are such as to favor extension of infection and reinfection of parts whose vital resistance has been lowered by disturbances of nutrition from any cause.—Dr. George R. Fowler, *Annals of Surgery*, November, 1896.

Abdominal Contusions with Visceral Lesions.—Dr. Gilliam (*Columbus Medical Journal*, March 16th) says that, in order that we may guard against such wholesale interference and still include as many as possible of the cases demanding operation, he has formulated the following rules. Explorative section should be made: 1. When blood is found in the ejecta of the stomach or bowels or in the urine. 2. When abdominal rigidity, tympanites, or other inferential signs of visceral lesion exists. 3. When the patient complains of burning pain or a sense of grave internal injury. 4. When there is profound, remittent, or recurrent shock. 5. When from the nature of the injury it is probable that visceral lesion has resulted. And finally the patient in all cases should be watched closely for forty-eight hours, during which time any untoward manifestation should be the signal for exploration.

Trephining.—Dr. Estes states that his experience leads him to believe that one should never use the trephine in depressed compound comminuted fractures. The instruments usually necessary are a knife, a pair of blunt-pointed scissors, a chisel, a good sharp Hopkins rongeur, two or three bone forceps with different curves, an elevatorium, two thumb forceps, one "rat toothed," a half dozen hæmostatic forceps, small and medium-sized curved needles and a good needle holder, small and medium silk, silk gut and catgut for sutures and ligatures. The small needles should be previously threaded and ready for instant use.

Acute Osteomyelitis.—Deep, rapidly increasing pain in an arm or leg, accompanied by swelling without redness or fluctuation, together with high fever or chills, is the typical picture of acute osteomyelitis. The disease at this stage, which may be a few days or only a few hours from its onset, is indeed one of the emergencies of surgery. The diagnosis must be carefully but fearlessly made and the treatment speedily instituted, for delay may mean death or lifelong deformity. No temporizing should be permitted once the diagnosis is clear, but free incision to the bone, with chiselling into its marrow, should be at once performed. You will not find pus, as a rule, in these early cases, but a periosteum which is easily peeled from the bone and a cortex which bleeds but little. Immediate relief of symptoms will show that you have not struck amiss. The frequency of necrosis of bone would be greatly reduced if these timely operations were more common. Unfortunately, the procrastinating poultice or the ice bag too often has its day, and in the mean time local tissue destruction and general sepsis may

compromise the case. Remember that any bone may be the seat of acute osteomyelitis, although it is oftenest encountered in the long bones.—*International Journal of Surgery.*

Enlargement of the Prostate.—In the ordinary cases of prostatic enlargement, of however long standing, in which the obstruction is not great and the power of the bladder is fair, in which there is not an excessive amount of residual urine, in which catheterism is easy and painless, and in which cystitis, if it exists, is not severe and can be controlled by aseptic washings and regular catheterism, operative treatment is not indicated.—SAMUEL ALEXANDER.

Torticollis.—Dr. Gillette (*Pediatrics*) reports three cases of torticollis due to adenoid vegetations and chronic hypertrophy of the tonsils. One case was cured by the removal of the local trouble and the others were greatly benefited.

Massage and Movements in the Treatment of Fractures.—Dr. Davis (*Annals of Surgery*, December, 1896) summarizes his views as follows: "It is my belief that massage and passive motion are not used to the extent that they should be in the treatment of fractures; that immobility of the fractured ends favors quick union with little deformity; that there are some cases in which, owing either to peculiarities of the fracture or the impaired constitution of the individual, the tendency to the formation of callus is marked. Motion in these tends to the formation of exuberant callus and deformity. There are others in which bony union is unduly delayed; disturbance of the fractured ends in these hinders union. It is wise to wait until the fractured parts are glued together, usually eight or ten days, before attempting any except the lightest massage, and any extensive passive motion after that time should be used carefully but diligently. Passive motion and massage, when first attempted, should be of the most gentle character, and not so violent as to disturb the relation of the broken bones. Any marked pain and inflammatory reaction following passive motion and massage are evidence that they have been too violent. The limb should receive massage and manipulation at each inspection or change of dressing, often daily. In some cases it is advisable to administer such massage as is possible without removing the splints. Persistent stiffness, particularly in fractures or injuries of the wrist, is often due to a rheumatoid affection locating itself in the injured region. Massage is valuable in the treatment of such, and should be given to that part of a limb beyond the seat of fracture to preserve it in a normal condition. Such dressings and methods of treatment should be adopted as will allow of the greatest use of massage, and passive and active movements consistent with proper retention of the fragments."

The Treatment of Injuries to the Gall Bladder and Biliary Ducts.—Drs. Terrier and Auvray (*Rev. de Chir.*, January, 1897) recommend operative interference in doubtful as well as in positive cases of injury of these parts. Laparotomy should be performed even though the question may arise whether a wound of the abdominal wall be a penetrating one or not, and also in cases of contusion when one suspects a rupture of any of these parts. Peritonitis caused by the effusion of bile is usually restricted and of a mild character, provided the fluid be aseptic; still there can be no doubt that bile, when in contact with the peritoneum, may act as a poison. Loss of bile resulting from the effusion of this fluid into the peritoneal cavity leads to exhaustion and emaciation, which will sooner or later threaten the life of the patient. Therefore in a case of abdominal contusion in which there is the least doubt as to the existence of a lesion of the biliary passages and in which there is pain localized in the epigastric or right hypochondriac regions, one should resort to prompt exploratory laparotomy. This operation, when performed with strict antiseptic precautions, is quite free from danger, and consists in a simple incision through the abdominal wall over the region in which the presence of effused bile is revealed by dulness and in the evacuation of the fluid. Caution must be taken not to wound any adherent intestine or any false membrane that may have formed about the seat of rupture. If the gall bladder be found torn through, one has to decide between cholecystorrhaphy and cholecystectomy, the former being practised for slight wounds and the latter when there has been much laceration. Rupture of the cystic duct should be treated by a ligature of the canal at its peripheral end and subsequent cholecystectomy. Rupture of the hepatic duct can be treated only by evacuation and temporary plugging and drainage, with a view of preventing further effusion into the abdominal cavity and the formation of protective adhesions. In case the common duct be opened it should be closed by a double ligature, and then a communication should be established between the gall bladder and the small intestines.

Silver as an Antiseptic in Surgical Practice.—Dr. Credé (*Centralbl. f. Chirurg.*, No. 43, 1896) advocates the use of silver and silver salts as safe antiseptic agents in the treatment of wounds. Gauze impregnated with finely divided silver may be used to cover the incision made in a surgical operation. If this is placed over ulcerated or freely secreting parts the silver is converted into the lactate of silver by means of the products of decomposition; this substance is very irritating. An open surface, therefore, is first covered by powdered citrate of silver and then silver gauze is placed over it to exclude the air. Credé states that this method of treatment does not require such strict precautions as other methods of antiseptic treatment. The results of this treatment have been very good and he regards the silver dressings as being the most reliable in the treatment of all forms of wounds.

The Best Method of Suture after Laparotomy.—La Torre (International Congress in Geneva) says: A good abdominal scar depends upon three main factors: the location of the incision, the suture material, and the method of suturing. Bantock: Bacteria take no part in the production of pus. They are the result and not the cause of the condition. Suppuration of the abdominal wound or the suture tract does not originate from the introduction of germs or adult bacilli into the wound, but is the sequence of necrosed tissue in the wound and excessive tension of the sutures. The ordinary interrupted suture suffices in most cases, but in very fat subjects it is advisable to close the peritoneal cavity with continuous sutures, while the rest of the wound is united by two layers of interrupted sutures. Silk is the best material for interrupted sutures, while for the continuous, catgut (not chromic-acid gut) is preferred. Byford: Avoidance of wound infection and injury to the tissue during operation is of prime importance. A median incision is advised. First unite the peritoneum, next fascia and muscles, and finally the skin. Use interrupted sutures of silkworm gut. Edebohls: The resistance of the abdominal scar depends upon a broad surface of contact. Divide the fibrous covering of the recti and in the subsequent closure of the wound the peritoneum is first united, next the two recti muscles are sutured together, and the suturing of the fascia and skin completes the operation. Use chromic-acid catgut for all

but skin sutures. Wylie: Hernia in the linea alba is frequently the result of abscesses, often caused by an excessive tension of the sutures. An exact suturing of the fascia is necessary; this should never be done by continuous sutures which would carry infection throughout the whole wound. Pozzi and Engström also lay great stress upon an accurate union of the same anatomical structures. Coelho considers deep silk sutures the best method, while Latzko demonstrates a series of microscopical sections of the abdominal scar which show that deep sutures unite many structures not anatomically related to each other, while a careful suturing of fascia to fascia and muscles to muscles, etc., leaves a hardly distinguishable scar.—*Indian Medical Gazette*, February, 1897.

Pyloric Obstruction of Hepatic Origin.—This rare sequel of cholelithiasis has been mainly acquired by exploratory operations. MM. Tuffier and Marchais record two cases and give a digest of those recorded by others. The calculous origin was clearly demonstrated in the whole series, except when the obstruction resulted from the mechanical pressure of an hepatic abscess or of a biliary cancer. An impaction of a calculus, whether in the bladder or in the ducts, may be followed by an ascending infection resulting in the formation of adhesions, with cicatricial contraction following, at times complicated by the development of fistulous openings between the gall bladder and the pylorus or duodenum. Symptoms of pyloric obstruction develop insidiously and may not appear until a long time has elapsed since the impaction of gall stones. The clinical features are somewhat the same as those met with in pyloric obstruction resulting from stricture and cancer. The vomited matter is very abundant, always containing free hydrochloric acid, and there may be a large amount of bile and even gall stones. In a small number of cases hæmatemesis is present. Dilatation of the stomach is pronounced. As the stomach gradually dilates, the pyloric obstruction may become complete and the patient dies of inanition, although recovery has occasionally followed upon the vomiting of a number of gall stones. The authors recommend washing out the stomach and other measures which may be conveniently described as medical; if no definite improvement follows, an exploratory operation is to be undertaken. The belly is to be opened in the median line rather than in the area of possible adhesions. The dilated stomach is to be displaced upward, which allows the region of the pylorus, the duodenum, and gall bladder to be explored; the latter may be found small, contracted, and united to the pylorus by adhesions, or there may be an ill-defined mass formed by the fusion of pylorus, duodenum, gall bladder, pancreas, etc., so firmly matted together that it is dangerous to attempt to separate them from each other; but if it is possible to separate these adhesions, it should be done with a proper sense of the risk involved. If, however, the obstruction at the pylorus is not relieved, a gastro-enterostomy, which affords the best means of relieving the symptoms, is to be performed.—Fevier, *Rev. de Chir. de Paris*, 1897.

Moribund Intestine.—Dr. Power (*British Medical Journal*, February 27, 1897), in an article on "The Pathology and Surgery of Intussusception," writes in regard to moribund intestine as follows: "When the surgeon has opened the abdomen and finds that the intussusception is greatly congested and has lost its gloss he must not too hastily assume that it is dead, yet it is often a matter of no slight difficulty to decide whether or not the bowel is capable of recovery. A piece of intestine which is only congested will bleed if it be pricked, even though it has lost its lustre, and if it be gently stroked until its vessels are emptied the blood will be seen to pass along the vessels again as soon as the pressure is taken off them. A piece of intestine in such a condition must be handled very tenderly. It is unnecessary to remove it, and the patient is often so collapsed as to render any prolonged operation impossible, even if enterectomy were advisable. The wisest thing to do in such cases is to wrap a layer or two of gauze round the injured intestine as soon as the invagination has been released. One end of the gauze is left hanging out of the abdominal wound, the intestine is laid inside the peritoneal cavity, and the incision is lightly closed with temporary silk sutures. If the bowel ruptures, the intestinal contents may then find their way out of the abdominal cavity, while if it recovers the gauze can be removed and the wound will close by granulations."

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

JUBILEE HONORS FOR DOCTORS—HOSPITAL SUNDAY FUND—MERCER'S HOSPITAL—HEALTH OF LONDON—COLLEGE SURGEONS—DEATH OF DR. RAMSKILL—THE HOSPITAL FUNDS—FILARIA LOA—CHARCOT'S DISEASE AND RHEUMATOID AFFECTIONS—ANTITOXIN IN DIPHTHERIA—HEALTH OF LONDON AND DUBLIN.

London, June 25, 1897.

Jubilee, jubilee all the week. It is over now so far as London is concerned, and the centre of its interest is the naval review.

Doctors have not been altogether omitted from the honors conferred on the occasion. No second medical peerage has been created, but some baronetcies and knighthoods are conferred and promotions in their orders of several who had already obtained such distinctions. These of course were largely represented by our military and naval brethren. The presidents of the two colleges receive baronetcies. Dr. Wilks, of the College of Physicians, was of course in every one's mouth as the one certainty, and we are all glad we were right. In fact, his claims could not be exceeded. Sir Wm. MacCormack had already been knighted and less could not be offered. The presidents of the two Irish colleges, Dr. Duffy and Mr. Thomson, receive knighthoods. A baronetcy is conferred on Mr. T. Smith—Tom Smith of Barts, as his friends have so long called the amiable and skilful surgeon. I wonder if they will drop the familiarity now he is Sir Thomas Smith, Bart. Dr. Gowers is knighted. His work has been worthy of even higher distinction. Dr. F. Semon attains the same honor. This is the surprise of the list, as he is a German, though some say that is the reason. He holds the German Red Eagle Order and founded a German periodical devoted to his specialty.

Among those promoted and admitted to orders are Dr. Thorne Thorne, C. B., who naturally receives the K.C.B. So do Inspector-General Norbury and Surgeon-General Gordon. In the case of the latter the distinction has been too long delayed. Dr. C. A. Gordon served through the Indian mutiny and in China with distinction and had been principal medical officer of Madras. He was sent to Paris with Surgeon-Major Wyatt, and they remained through the siege and felt all its horrors. The ambassador did not remain, but fled to Lyons, leaving there two surgeons as our representatives. The wretched government of that day never recognized their service—it is said for fear of reflecting on the ambassador. At length the present government repairs the neglect

as to the survivor, and Dr. Gordon, C.B., becomes Sir C. A. Gordon, K.C.B., but poor Wyatt has long been in his grave. Mr. Burdett of hospital fame and Professor Crookes also get K.C.B., and as their work is so related to ours they may be included in our congratulations. Dr. Grimshaw, registrar-general for Ireland; Dr. Nicolson, visitor in lunacy; Major-General Jameson, director-general; Sibthope, Indian medical service; and MacNalty, army, receive the C.B. Among the other orders the medical names are Mackie, Egypt; Bushell, Pekin; Brown, colonial office; Rowland, Lagos; Hooker, Kew; Hooper and Cleghorn, India; Husband, Ajmere; and Inspector of Fleets H. C. Woods. Dr. Haffkine's labors in India are recognized by a C.I.E.

The Hospital Sunday Fund up to this date has amounted to only half as much as in the corresponding week last year. But probably the suspension of business proceedings through the jubilee has prevented the remittance of the collections and they may be larger next week.

As was to be feared, there are several candidates for Mercer's Hospital, who are ready to fill the vacancies on the condition of being equally ready to be dismissed whenever the non-medical board may please. Sad to say, some whose assured position should make them equal to refusing such terms are willing to "bow the knee" to the gods in possession. Will not the Irish profession boycott them?

The health of London just now is a source of congratulation. Last week the mortality rate fell to 13.4 for 1,000. The previous week it was only 14.8. We may take the average of the whole country as about 19, though in many places it is only 16, in others 14, and in some it has touched 12. Our present figures have been well contrasted with the 80 per 1,000 of Queen Elizabeth's time.

Lister declines the projected nomination for the Council of the College of Surgeons.

The death is announced, on Jubilee Day, of Dr. Jabez S. Ramskill, many years physician to the London Hospital, a member of the College of Physicians from 1853, and from some strange prejudice never made a fellow. He was long physician to the Hospital for Paralysis and Epilepsy, and contributed many papers on nervous diseases.

London, July 2, 1897.

The Prince of Wales' hospital fund has done well this week. Yesterday checks for £5,512 15*s.* 6*d.* were received from the Freemasons of England as the result of a great meeting of the order lately held at the Albert Hall, under the presidency of the prince as grand master of Freemasons in England. These contributions from the grand lodge are in addition to many gifts from different lodges and chapters, as well as from individual Freemasons. This morning it is also announced that the annual subscriptions promised to the fund amount to £2,449 10*s.* 3*d.*; donations, £132,598 14*s.* 9*d.* Commuted subscriptions, to be invested, £20,554 2*s.*

The Hospital Sunday fund has much increased during the week, but still lags behind the amount received in the same period last year. It is hoped that this is only on account of delay in remitting, caused by the interruption to business of every kind during the jubilee week.

Filaria Loa is rare enough to excite continuous interest in any case. Two years ago Dr. Argyll-Robertson reported one, and he has lately related to the Ophthalmological Society its subsequent history. The patient went back to Old Calabar, and forthwith her symptoms returned. Itching behind the eyes and swellings in the arms were prominent, and are said to be almost universal in the Gaboon. Once the patient felt a bite in the night, and immediately extracted a portion of the worm. Movement of a parasite was felt under the conjunctiva. On two occasions the knuckles were incised in search for one felt moving. As lately as last May one was felt near the umbilicus, but could not be secured. When the parasites are felt moving, headache, nausea, and puffy swellings of the arms are troublesome. All parts of the body seem affected, especially the scalp. The blood, saliva, nasal mucus, and excreta have been searched unsuccessfully for embryos. I hear that two cases were lately under Dr. Manson's care. The life history of this parasite has yet to be made out.

The relation of Charcot's disease to chronic rheumatic arthritis seems still uncertain—some holding it to be merely a variety, others regarding it as in no way related. The question was lately before the Royal Academy of Medicine in Ireland, *à propos* of a case exhibited by Dr. Conolly Norman, with skiagraphs showing the condition of the bones. He thought perhaps some nervous affection is in such cases associated with the rheumatic disease. This would be an approach to the view of those who look upon chronic arthritis as altogether a neurosis.

Dr. Norman said he had seen only one case of Charcot's disease in Dublin, but had examined his specimens at the London congress. He thought the destruction of bone was much greater than in rheumatic arthritis, but nevertheless the disease was pathologically the same, except that there was more effusion in rheumatism in these islands, but he said this was not so in France, as shown by the term *arthrite sèche*. I fancy, however, this term only belongs to one stage of the disease, for great variety in respect to effusion is observed in different cases, and the majority are characterized by a dry stage at some period of their long course. Dr. Finny thought Dr. Norman's case must remain at present in an unknown category. The degree of effusion in the joints and the backward movement of the leg differentiated it from the very few cases of Charcot's disease he had seen. It was not easy to test the knee jerk, and the mental condition was against tabes. The patient was not affected in the upper limbs, but they might become involved later. It was afterward remarked that the only symptom of tabes present was the Argyll-Robertson sign, and there was much anæsthesia of the legs, which is suggestive of alcoholic neuritis. Altogether the case is interesting, and, considering the prevailing confusion respecting the relation of various diseases to the rheumatic group, well worth watching.

In the Harben lectures at Kings College, Dr. Sims Woodhead has discussed the antitoxin treatment of diphtheria. On Wednesday he exhibited specimens of degeneration of tissues produced as early as the third and fourth day of the disease, and observed that when such changes have taken place we cannot expect rapid restoration. This accounts for the necessity of early treatment, as the serum decreases in power with every day of delay. In the presence of both toxin and antitoxin, these destructive changes do not occur. He held that the serum is preventive as well as curative, and would recommend its use as a prophylactic to persons exposed to infection. He enforced the necessity of early treatment by statistics showing great differences in mortality according to the day on which it was begun. Even in cases which had been neglected until the fifth day, there is a reduction in the mortality of 6.2 per cent., and he declared that those who oppose the use of the serum "assume a tremendous responsibility."

London is maintaining its exceptionally low rate of mortality. The health of Dublin has undergone a remarkable improvement. It is not long since I mentioned the epidemics there and the terrible mortality rate of 42 per 1,000. It has now dropped to 19.7.

OUR BERLIN LETTER.

(From our Special Correspondent.)

HOT WATER IN DISEASES OF THE SKIN—EXCESSIVE TREATMENT IN DISORDERS OF INFANTS—HOSPITALS FOR INFANTS—NUTRITION AND PUTREFACTIVE PROCESSES IN THE INTESTINES—A UNIVERSAL ANTISEPTIC FOR INFECTIOUS DISEASES—MEASUREMENT OF PUS IN THE URINE—TRAUMATIC DISORDERS OF THE HEART.

June, 1897.

A FURTHER proof of the tendency to abandon the purely medicative treatment of diseases for hygienic and dietetic methods has been recently furnished to us by Rosenthal in a paper upon "The Therapeutics of Hot Water, Especially in Diseases of the Skin," read before the Verein für innere Medicin. The physiological effect of hot water upon the organism consists principally in an increase of the waste products, brought about by the stimulation of the circulation, an increased exchange of the gases, etc. This effect points out to us the indications for its employment. Contraindications are heart disease, angina pectoris, atheroma, etc. Good examples of its beneficial effects are seen in hot forehead baths in migraine and hot douches in uterine hemorrhages. Observing that a soft chancre in feverish patients always heals quickly, Rosenthal was led to employ hot water in the treatment of this affection. *Per se*, it will not heal, but it aids the healing very remarkably. It has been further suggested to employ hot water in the treatment of gonorrhœa, but thus far no reports have been handed in. The bactericidal working of hot water is especially noticeable in favus and stinking abscesses of the feet. Of great benefit is its employment in pruritus, chronic urticaria, various forms of eczema, and notably in acne vulgaris and acne rosacea.

Neumann, the well-known pædiatrist, has come out strongly against the too zealous employment of water in the treatment of infants. He maintains in his article upon "Excessive Treatment in Disorders of Infants" that the early removal of the vernix caseosa is a wrong procedure, because it is aseptic. The first bath should therefore be given after the navel wound shall have healed. Neumann also speaks against too active cleansing of the mouth, too much rubbing and scrubbing; also against the loosening of the frænum linguæ, which is so often unnecessarily done. He protests especially against scarification of the gums in the belief that dentition is the cause of many diseases. He deserves our thanks in thus combating the abuses in infant therapeutics, and in thus lending weight to the maxims "Ne nimis" and "Primum nil nocere."

The subjects of "Infantile Feeding" and "Hospitals for Infants" have been recently taken up by Professor Huebner. He warns against too much dilution in artificial milk feeding, as the infant thereby receives too few calories. He takes stand against hospitals for young infants; in them the mortality is considerably higher than in families. He found the cause to be an infection of the children through the nurses, under the fingernails of whom he demonstrated the presence of large numbers of the bacillus coli communis. He ordered thereupon that those nurses who cleaned the children should not feed them, with the result that the mortality receded from eighty per cent. to sixty-five per cent. He therefore views in the establishment of hospitals for suckling infants a great danger; but, as their establishment is a social necessity, he believes the dangers may be minimized by having smaller wards, dividing the nursing-service, admitting the mothers, etc. In the discussion to which his article gave rise the foremost pædiatrists of Berlin participated, and all conceded the justice of Huebner's stand against these institutions. Especial attention was called to the large mortality among the illegitimate children of Berlin. The cause is to be found in the want of attention and the lack of care in the preparation of the food, as a result of which the children fall victims to intestinal catarrh.

Albu has recently shown in a paper read before the Verein für innere Medicin, entitled "Relationship of Intestinal Putrefaction to the Nutrition," that in disorders of this nature prophylaxis is the chief thing. Intestinal antiseptics and intestinal disinfection, in the true sense of the word, do not exist: all attempts to prevent intestinal decomposition and putrefaction by means of internal medication have proven futile. This applies to enemata as well. The best results are obtained from laxatives which remove decomposing contents, or at least the greater part. Albu made two series of investigations: first, the influence of sterilized food; secondly, the influence a strict milk diet. He found that only after good previous catharsis would the intestinal decomposition during a sterilized diet become decreased from that resulting from an ordinary diet. Of course this is not adapted to ordinary living. The decomposition after a milk diet, on the other hand, was markedly diminished. A variety of experiments showed that this result was owing to the sugar of milk present in the milk, working either as a laxative or as a specific intestinal antiseptic. This antiseptic action finds its explanation when we consider that the milk sugar, together with the albumin and fat of the milk, is brought into intimate contact with all parts of the intestines, and splits up into the strongly disinfecting lactic acid. Still the milk sugar cannot prevent the intestinal decomposition, as the latter is dependent upon a great variety of circumstances (quantity, composition, and quality of the nutrition, frequency of meals, number of stools, etc.), and also because the addition of other food stuffs interferes with the working of the milk sugar. In practice we must therefore refrain from any attempt to disinfect the intestines through medication.

Professor Posner, who believes it necessary to make quantitative tests for pus in the urine, has devised a method for this purpose. He estimates by means of the transparency of the urine. The urine is placed in beakers, each beaker being placed upon or before a paper with writing or printing upon it; each glass is filled with the urine under examination until the writing or printing can no longer be read. An empirical scale has been devised and is used as a standard of comparison. As a second method of estimating pus, Posner employs the Thoma-Zeiss apparatus for counting the pus cells.

It is also of interest to note a case reported by Litten which illustrates the possibility of a traumatic heart disease. A soldier in active service received a kick from a horse in the region of the heart and was brought into the hospital, where he was found to have an acute endocarditis. He convalesced. Nine months later Litten examined him and found an increase in size of the right and left sides of the heart and systolic mitral and aortic murmurs. He made the diagnosis of mitral regurgitation and endocarditis. Litten has no hesitation in pronouncing this case as one of indisputabe traumatic endocarditis. As a result of the kick either the valves were torn or the endocardium was loosened, and thrombi formed at the place of laceration; these last organized and thus produced the vitium cordis. Of course the patient was entirely well prior to the accident, having passed the military examination.

Kossmann recommends the injection of a drachm of glycerin within the cervix to induce labor.

MEDICAL EDUCATION IN AMERICA AND GREAT BRITAIN.

To the Editor of the Medical Record.

Sir: I have just read your editorial in the Medical Record of July 3d, and am astonished that you seem to consider New York the sole State having interest in advanced education. You evidently have forgotten the battle made by the University of Pennsylvania for this high standard, and, as I am very familiar with both your New York schools and those of Philadelphia, I unhesitatingly say that, should any be singled out for conspicuous leadership, that one should be the University of Pennsylvania. Your article is most unfair to Pennsylvania schools in general and to the University of Pennsylvania in particular. Having had opportunity to see something of English schools, too, I am forced to conclude that it is not of inferior standard compared with any of them.

I trust you will see your way clearly to present your readers these proper objections to your editorial position.

S. S. Koser, M.D.

Williamsport, Pa.

[Our correspondent is in error in supposing that we intended any reflection upon the University of Pennsylvania. We merely stated in passing that New York was well in the front in medical education reform. We made no invidious comparisons, and are perfectly willing to admit the good work of the university in question, and also of the Harvard Medical School, for that matter. It strikes us that our correspondent is a trifle too sensitive to be reasonable.—Ed.]

FORT'S LINEAR ELECTROLYSIS.

To the Editor of the Medical Record.

Sir: At a meeting of the New York County Medical Association on March 15, 1897, a paper was read by Dr. Newman, on the application of electrolysis in the treatment of stricture of the urethra. The paper in question was called forth by what occurred during my visit to the United States toward the end of the year 1895, when in the clinical practice of Dr. R. W. Taylor, at Bellevue Hospital, I performed a number of electrolytic operations for urethral strictures. In view of the success attending my treatment, Dr. Taylor procured for me the privilege of reading a paper before the New York Academy of Medicine, the members of which declared themselves distinctly in favor of the methods adopted by me.

It is with the statements made by Dr. Newman in his communication above referred to that I now purpose to deal.

Dr. Newman, first of all, contests my right to be considered the true inventor of my electrolytic instrument, which he says is exactly identical with that of Dr. Butler. (It is described in the *American Journal of Electrology and Neurology*, vol. i., No. 2, October, 1879, p. 95.) Butler's instrument is a hollow tube with a slot, in which are two wires that may be brought together by means of a screw, or separated in such a manner as to form an ellipse. This ellipse, owing to the great flexibility of the wires, adapts itself to the shape of the stricture.

I will not enter into further details of Dr. Butler's electrolyzer, since those who are acquainted with mine will see from the above that the two instruments are altogether different.

Dr. Newman criticises my electrolyzer adversely on the ground that it possesses only one blade for different-sized strictures. This is a serious error, for I have electrolyzers of different sizes, large and small. Furthermore, I will add that my own experience teaches me that a small blade may be used to dilate the canal just as well as a large one, because the muscular fibres of the urethra contract when the blade touches them, so that it is the stricture which is electrolyzed on the blade and not the blade which acts upon the stricture.

Dr. Newman does not consider that the current which I use—ten milliampères—is sufficient to break down the stricture. To this I will reply by using the argument which Dr. Newman himself puts forward in defence of his process: "The success of electrolysis in urethral strictures is so well established that simple negations cannot undo affirmations." From the objections made by Dr. Newman, it is evident that he does not understand my process and has never seen it applied.

In regard to Dr. Newman's question as to the maximum intensity of current that may be used, I will say that I have not experimented with a view to elucidating this point; but the intensity depends upon the patient's power of resistance, and in our current operations I have seen the galvanometer register as much as forty milliampères, and this without ill effects. The operation is effected just the same, while the pain is not sensibly increased.

If Dr. Newman understood my *modus operandi*, he would not accuse me of practising divulsion; for I always recommend the operator not to force or push the instrument, but simply to hold it steady. If divulsion occurred, there would be pain, tearing, and hemorrhage; but there is neither pain nor hemorrhage, and consequently no tearing.

"Now," says Dr. Newman, "the question arises, Can a current of ten milliampères for thirty seconds enlarge a stricture eleven numbers, or even less, by electrolysis; or is the enlargement due to the force used, thereby being a divulsion?" To this question I will simply reply that I enlarge not only eleven numbers, but up to eighteen or nineteen, and without using any force. I have a considerable body of notes relative to patients with almost impassable strictures, through which, after the operation, I was able to pass a No. 22 bougie, and even a No. 24, French scale.

Dr. Newman claims to test the effects of my process by means of chemical experiments, but I will not enter into the discussion thereof, because they are altogether negatived by the facts. In my work, "Traitement des Rétrécissements par l'Electrolyse Linéaire" ("Treatment of Stricture by Linear Electrolysis"), I have published a large number of observations which effectually silence the objections made by Dr. Newman against my *modus operandi*.

To sum up: Dr. Newman's objections to my operative methods have no value, because they are theoretical and in complete contradiction of facts, and also because he does not appear ever to have performed my operation.

In its action my instrument resembles to some extent Maisonneuve's urethrotome, which was so universally recommended. It differs from this latter only in that it does not cut and does not tend to produce any of the accidents so frequent after urethrotomy.

The success of the operation depends upon the form of my instrument, which acts upon one single line and with great swiftness, like the urethrotome of Maisonneuve. But the tightest strictures may be operated upon, provided the guide bougie can pass through.

Any soft stricture may be managed with a current of ten milliampères, and without the slightest forcing. In order to prevent relapses, it is necessary to pass a bougie along the canal from time to time. Up to date I have operated upon some thirty-five hundred patients, and my record cannot be affected by a simple statement.

J. A. Fort, M.D.

Paris, [illegible]

REPORT ON HYDROPHOBIA.

To the Editor of the Medical Record.

Sir: Dr. Charles W. Dulles, in his report on hydrophobia, writes to your journal under date of June 26, 1897: "The accumulation of these cases has required a great deal of labor, and I have taken pains to verify, as far as possible, the facts, and to correct the errors of published accounts by correspondence with the physicians who have had the care of the cases." Dr. Dulles has had a number of personal interviews with the writer during the past year, and yet he says, in his description of an "interesting case": "The opinion was positively given by the bacteriologist and by the coroner's physician that the dog was rabid and that the child was in great danger. The father was advised to send the child to New York." These three statements require contradiction. I never saw the dog, never performed any experimental inoculations, and never even examined the child. In my talk with the father pending a consultation, the danger was minimized and the child was advised to go not to the Pasteur Institute at New York, but to the country or seashore. The reader will readily decide between the high professional standing of an experienced bacteriologist, such as Dr. Bolton, and the veterinary surgeon who says the dog was suffering from hydrophobia and the pound keepers who say the dog had "fits."

Henry W. Cattell, M.D.

Philadelphia.

TREATMENT OF TIC DOULOUREUX.

To the Editor of the Medical Record.

Sir: *À propos* of the letter to Dr. Charles L. Dana published in the issue of June 26th, I would say that I have used large doses of strychnine, hypodermically and by the mouth, for some time, with gratifying results in the treatment of tic douloureux. It may be worth recording that one of the most marked cases is in an old lady, at present under treatment for the second time in the past three years. She is seventy-nine years of age, and has had attacks for fifty years up to the institution of treatment. She had been free up to this spring for the past two years, but during my absence for post-graduate work her attacks recurred but not with old-time violence, but their severity was increasing. Previously I had never exceeded one-twentieth grain *ter die*, but owing to the seeming urgency I gave her one-twentieth grain by mouth morning and noon, and one-fifteenth hypodermically in the afternoon. This was followed for one week without any toxic symptoms and with marked decrease of pain after the second day and entire freedom now for four days, this being the thirteenth day since my return. Previously she had not slept for weeks except an hour or two at night. In her old-time attacks she could neither eat nor speak, the muscular effort bringing on the spasm. She at present takes one-twentieth grain *ter die* by mouth.

The interesting points are the advanced age, the heroic doses, the absence of toxic symptoms, and, most important, the almost immediate relief from pain.

J. H. Greene, M.D.

[illegible]

Quinine in Suppositories.—Quinine, ten to twenty grains, in suppositories per rectum, gives good results without the production of the nausea, headache, singing in the ears, etc. It should be given in this manner in all cases of fever in which quinine is indicated, and especially in malaria and in the case of children. —T. Dunbar Brunton, *British Medical Journal.*

New Instruments.

A NEW URETHRAL SOUND.

By Charles C. F. Niesmann,

[illegible]

Sexual neurasthenia, atonic impotence, frequent emissions, premature ejaculations, imperfect erections and erections of short duration, are in many cases caused by an extremely hyperæsthetic prostatic urethra or by chronic prostatitis. Prostatorrhœa has a bad effect upon the mind of the patient believing himself the victim of spermatorrhœa. The most frequent cause for this condition is excessive venery or posterior urethral gonorrhœa.

The treatment with aphrodisiacs and sexual stimulants is contraindicated and in many cases very injurious.

"The most effective means of relieving the irritability of the prostatic urethra is the systematic introduction of full-sized steel sounds," Morrow's system, which overcome the hyperæsthesia and relieve congestion by distention and pressure and contact of the cold sounds. Most of these cases are complicated with spasmodic strictures, either from the nervous condition of the patient or from reflex irritations of the urethra. The passage of a cold sound will in a great many cases bring on urethral spasm resisting the farther introduction of the instrument, whereas a warm sound will pass quite easily. I have observed this condition often and have been led by it to devise this instrument. It can be passed warm and then be immediately cooled.

The instrument consists of four hollow sounds, Nos. 12, 14, 16, and 18 French, with one universal handle with two small tubes projecting for connection with a fountain syringe by a piece of rubber tubing.

The manner of using the sounds is obvious and needs little explanation. The handle is attached to the sound of proper size. It is warmed and passed into the urethra; a fountain syringe filled with ice water is attached, and the outflow tubing is shut off until the sound is full of water, when it is slightly opened.

I have had unexpected good results following this treatment, without internal medication except regulating the kidneys and alimentary tract, with hygienic and dietetic regulations.

The instrument was made for me by Messrs. Tiemann & Co., New York.

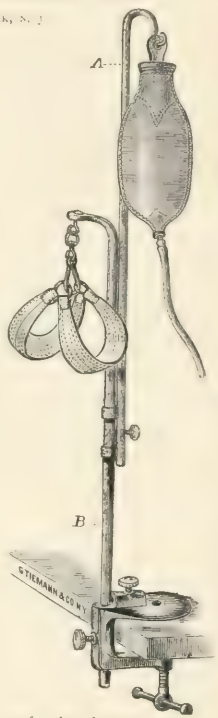
I will add my mode of lubrication. The usual way is to apply vaseline or some bland oil to the surface of the urethral instruments. Now the meatus, being the smallest part of the urethra, it rubs off and retains the lubricant, and beyond the orifice the instrument passes comparatively dry. Instead of oiling the instrument, I take an ordinary medicine drop-

per and draw it full of vaseline oil, slightly warmed; inserting its point into the meatus and holding the organ perpendicular, I press the oil into the urethra.

NEW SUSPENSION DEVICE FOR IRRIGATOR USED IN CONNECTION WITH THE EDEBOHLS LEG SUPPORTER.

BY HERMAN C. BLEYLE, M.D.,

NEWARK, N. J.



In order to do away with the inconvenience so often met with in the performance of gynæcological work at the homes of patients, in obtaining suitable means of suspension for the irrigator, the writer has had constructed by Messrs. Tiemann & Co., an extension rod, with hook, *A*, which when clamped on one of the upright bars of the Edebohls leg supporter, *B*, very effectively answers the purpose of furnishing needed suspension facilities. This device allows the operator to place the table in the most convenient position as regards light and his own comfort, and relieves him of the necessity of depending on some suspension point inconveniently situated. It can also be utilized in many of the usual surgical operations in which an ordinary table can be used and constant irrigation is required. The mechanism of the instrument explains itself.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 10, 1897:

	Cases.	Deaths.
Tuberculosis	164	109
Typhoid fever	10	0
Scarlet fever	107	7
Cerebro-spinal meningitis	1	1
Measles	150	2
Diphtheria	238	30
Laryngeal diphtheria (croup)	10	4
Chicken-pox	8	0
Small-pox	0	1

Aqua Tofana.—Murrell says that the aqua Tofana made and sold by the iniquitous Tofana or Tophiana, who is supposed to have poisoned with it more than six hundred people, including two popes, Pius III. and Clement IV., was made by rubbing white arsenic into pork and collecting the liquid which drained from it during decomposition. It is probable that in the process a ptomain or cadaveric alkaloid was formed, possessing properties of the highest degree of toxicity Long after Tofana's death it continued to be made at Naples and to be distributed secretly throughout Italy. It was used by Hieronyma Spara, an old fortune teller, who was presidentess of a society of young married women, whose diversion it was to poison their own and other women's husbands. Marie de Brinvillier's poison contained arsenic, and it was the active principle of the *poudre de succession* or inheritance powder for which at one time there was an extensive demand. —*Medical Brief.*

The Thumb and the Brain.—Dr. Burton Ward declares there is one infallible symptom indicating whether one is sane or not. Let a person speak ever so rationally and act ever so sedately, if his or her thumbs remain inactive there is no doubt of insanity. Lunatics seldom make use of their thumbs when writing, drawing, or saluting.

The Prognosis of Drug Habits.—The morphine habit becomes practically incurable in five years. The user of alcoholic spirits may continue eight or ten years before he reaches the incurable stage. This will depend on the free intervals between the time of using spirits. When he becomes incurable he may abstain, but the injured brain and nervous system never recover.—*The Quarterly Journal of Inebriety.*

To Remove Nitrate of Silver Stains from Clothing.—A solution of iodine in ammonia water, the so-called colorless tincture, will remove nitrate-of-silver stains from the hands, clothing, etc., but owing to the danger of the formation of nitrogen iodide, which is a powerful explosive, it is not recommended. A solution of iodine in iodide of potassium dissolved in water is nearly as quick and quite as effective. Dissolve fifteen parts of iodide of potassium in fifty parts of water, and to the solution add ten parts of iodine. When the latter is dissolved add sufficient water to make five hundred parts. Keep in a well-stoppered bottle. Treat the spots with this, and after a few minutes with a ten-per-cent. solution of caustic soda, which will remove the silver iodide formed by the first treatment.—*The National Druggist.*

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service during the week ended July 10, 1897:

SMALL-POX—UNITED STATES.

JACKSONIAN EPILEPSY; ADENOMA OF LIVER; ACUTE ASCITES WITH TUBERCLE BACILLI.

BY A. JACOBI, M.D.,

NEW YORK.

A. A—— was born August 7, 1885, and died January 16, 1897. Her father was always in good health, her mother at one period of her life neurotic. Father's family was without any morbid taint; mother's ancestors died when seventy-five, eighty-five, and ninety years old. She is the youngest of ten boys and girls, none of whom died young. One sister died of cerebro-spinal meningitis, one of "fistula" after having been insane, one brother (the oldest in the family) was an army officer during the civil war and died insane. Of the seven now alive one, a man of great abstract learning and a college professor, with healthy children, is epileptic.

A. A—— weighed eight pounds at birth, sixteen when six weeks, twenty-eight when ten months old. Her first teeth (lower incisors) appeared at six months; the others, both temporary and permanent, came in due order and without any trouble. She walked when a year old. She was wetnursed, never perspired on the head, lost no hair, had no thickened epiphyses, her limbs were straight. The only symptom reminding of rickets was constipation, which appeared at the age of six or eight weeks, and required enemata until she was five years old. At three years of age she had whooping-cough; at four, measles; no other disease.

In September, 1891, she fell from a swing, hurting the left side of her head. She did not get pale or vomit; she cried, and appeared uninjured. In January or February, 1892, her right hand was noticed to twitch a little. In November she began to take music lessons; the twitching became stronger and more frequent, and the lessons were discontinued. On November 1, 1893, she had on waking in the morning the first hard attack of convulsions, probably with loss of consciousness. The second attack of the kind took place on the 16th. There was complete loss of consciousness and slow recovery. Thick, incoherent talk; slight paralysis of the right arm. During two days previously the child, who was remarkably observing and intelligent, had noticed fatigue and pain in her right arm, and told a playmate she was going to have an attack. On November 24th she complained of tiredness and numbness in both arms, more so in the left. She slept poorly during that night, and experienced slight twitchings in her right hand. Feeling an attack coming on at 6:30 A.M., she jumped up with the idea of preventing it. It was slight, with no loss of consciousness. Slight stiffness of legs. She said she had to hold on to the foot of her bed, as she was not quite steady. Afterward she felt absolutely well, and played all day. She had taken bromides two days; they were continued in moderate and later on in larger doses, so as to give rise to bromism repeatedly. Slight twitchings of the right arm in the night of February 18, 1894. March 9th, while running, she tripped and fell, striking her right arm heavily. She complained at once of twitchings, which, though slight, continued over an hour. She was put to bed, but she complained of their coming more frequently while she was lying down; tying a cord round the arm above the elbow made the twitchings stronger. She seemed very nervous and worried each time the arm twitched. When she was read to the shaking stopped instantly, and she was well all day. Evidently this attack had but partly the significance of the former ones. The right arm shook badly on waking April 4th, after she had been playing, skating, and falling several times the previous afternoon; again on April 13th and May 22d. During two days previously she had complained of fatigue and pain of her left hand. She had been writing a good deal, however, with her left hand previously, having been taught and accustomed to use her left hand in place of the right when the local convulsions began. Slight attack on the 27th, two on June 2d.

Most of the attacks would come on in the morning on waking up; they lasted mostly a few minutes, and were but rarely attended with unconsciousness. She would often laugh and joke immediately afterward. During most of the attacks, and often days before, the child was pale; sometimes she was irritable before or after them, in some instances for days. But very few times she had more severe attacks during her sleep, breathing heavily and shaking all over her body. Before she was taken to Europe in the summer of 1894, she had, however, only very few of these hard attacks. Up to this time, and also later, she enjoyed the occasional advice of Dr. S. Weir Mitchell, who saw her both in Philadelphia and in New York. Drs. Gowers and Jackson saw her in London. It was principally the former who objected strenuously to the performance of an operation, the advisability of which had been suggested.

During her European trip she was not changed. Slight attacks would come, mainly when she was, or had been, fatigued; five during August, 1894. After three slight ones, on her return, she had a fully developed epileptic attack in her sleep on October 26th. After a few slight ones, in January, 1895, the attacks ceased entirely while she was taking, first fifty, afterward sixty grains of bromides daily, together with lithia and valerianate of zinc. The bromides having disagreeable effects (as heaviness, drowsiness, bloated face), were discontinued June 8th, and valerianate of zinc only administered. Attacks returned—one on the 25th, two the 26th, three the 27th, four the 28th, six the 29th, four the 30th (wetted the bed the first time), six on July 1st (was given again bromides, 60 grains daily; zinc valerian, 30 grains; atropine, $\frac{1}{120}$ grain), six on the 2d and on the 3d, nine on the 4th and on the 5th, five on the 6th, and three on the 7th. The bromides again showing a disagreeable effect, they were diminished, and the daily medication consisted of 30 grains of the bromides, 15 grains of valerianate of zinc, 10 grains of zinc oxide, and $\frac{1}{100}$ grain of atropine.

No attacks until December 21st (slight) and 22d

(hard), after which she was given 60–70 grains of bromides daily, and 30 grains of valerianate of zinc, for one week. They were then stopped a while; the attending physician, who saw her often every day, changing the medication as circumstances appeared to demand.

During 1896 the case changed for the worse. There was a severe convulsion on January 2d; it began in the right arm, and was mostly confined to the right side. Unconsciousness lasted but a few minutes, but there was great weakness and numbness of the right arm. It is quite important to remark that her intellectual faculties suffered very much less than the arm from an attack. On the 3d there was a severe local convulsion of the right arm without any unconsciousness, and one slight attack each on the 15th, 16th, 18th (two attacks), and the 20th. On the previous night her pallor was excessive and her pulse feeble. In February she had twenty-one attacks of shaking or twitching of the right arm (one of the fingers of the right hand only) on ten days altogether. During March, 1896, the attacks, all of them localized, no general convulsions, became both more numerous and more severe. She had four on the 1st, five on the 2d, three each on the 3d, 4th, 5th, four on the 6th and 7th, six on the 8th and 9th, seven on the 10th, eleven on the 11th, fourteen on the 12th, twenty-seven on the 13th, twenty-six on the 14th, twenty-nine on the 15th, forty-nine on the 16th, twenty-five in the night of the 17th, twenty-six on the 18th between 7 A.M. and 9 P.M., twenty-eight on the 19th during the same hours, and nineteen in the following night. The last few days many of these local convulsions were attended with heavy breathing, the body was often drawn to the left while the right arm was drawn up or shaking, or both, and on the 19th the mouth was noticed to be drawn to the left.

It was on that day that Dr. Charles A. Dana saw the patient. To his kindness is due the following report:

"The patient was seen by me, March 19, 1896. She was a well-grown girl for her years, and apparently well nourished, but quite anæmic. Her mind was particularly bright and mature. She had a slight weakness of the right arm, but no paresis of the facial muscles or of the legs. The knee jerks on both sides were normal, not exaggerated on the right side. The right arm showed a certain amount of ataxia. There was an inability to place the finger easily on the tip of the nose with the eyes closed, or perform delicate muscular movements, such as buttoning the clothes or picking up small objects from the table. There was also a slight lack of localization sense, so that she could not determine exactly the point touched by the hand or arm. There was, however, absolutely no anæsthesia—no loss of touch, of pain, or of temperature sense. The elbow jerk was present. There was no atrophy or any tremor or spasmodic movement in the arm. The tongue protruded straight, and there was no asymmetry of the facial muscles. The patient had no concentric limitation of the visual field or aural field, no loss of sense of smell or taste, no pharyngeal anæsthesia; in fact, absolutely none of the stigmata of hysteria. There was simply the weakness of the arm, with ataxia and defect in 'motor touch,' such as is found in disease of the motor cortex. During the examination she had several slight convulsive attacks; the arm was extended, the forearm pronated, the hand flexed, and the whole arm separated somewhat from the side. The head was drawn over, to some extent, to the same side; but the eyes did not move. There was some twitching of the muscles of the face of both sides. There was no biting of the tongue, and had not been. The attack came on suddenly, and without cry or distinct aura; the patient asserted that it was not accompanied by loss of consciousness. It lasted only one or two minutes. After it was over the arm was for a time almost paralyzed, but after a few hours gained considerable strength. She would have a number of these attacks during the day. Shortly after my visits began they ceased, however, and the arm grew gradually stronger, less clumsy, and eventually she could use it nearly as well as the left, though never quite the same.

"The attacks were quite typical examples of a Jacksonian epilepsy. She had had at no time any severe headaches, no vomiting, and had no optic neuritis. The diagnosis at the time was Jacksonian epilepsy, due probably to some slight degenerative changes in a limited area of the motor cortex."

Under the direction of Dr. Dana she took, on March 20th, nitroglycerin, $\frac{1}{100}$ grain; and urethan, 5 grains, every two hours; bromides, 50 grains, through the day. She had thirteen severe attacks through the day (they had since becoming so numerous been more frequent during the day), and nine in the night; on the 21st forty-five and fifteen (bromides, 45 grains; urethan, 45 grains; nitroglycerin, 6 tablets of $\frac{1}{100}$ grain); on the 22d thirteen hard attacks and thirty-three slight twitchings from 6 A.M. to 10 P.M.; six times the right leg shook with the arm. There were four slight attacks in the following night. Medication—bromides, 35 grains; urethan, 50 grains; nitroglycerin, 7 tablets. On the 23d there were forty-nine slight twitchings between 8:30 A.M. and 10 P.M.; none in the night. Medication—bromides, 30 grains; urethan, 55 grains; nitroglycerin, 3 tablets. The child was much brighter and stronger. On the 24th there were twenty-one slight twitchings between 7:30 A.M. and 9:30 P.M. Medication—bromides, 30 grains; urethan, 60 grains. On March 25th and the following days the same medication and no attack whatsoever at any time. On April 1st albuminuria was noticed, and urethan was given in doses of 45 grains; on the 3d less albumin —urethan, 30 grains. This dose was continued. On the 6th there was hardly a trace of albumin and the appetite was good. At the same time daily doses of 30 grains of bromide were given; from July 5th to July 11th she took 25, after that 20 grains daily.

It should be here remarked that during the time of the greatest number and severity of the attacks large doses of bromides, up to 100 or even 120 grains, were given daily, with or without the valerianate of zinc, and had often to be discontinued because of serious bromism. The only time in which the attacks ceased and the patient felt better at the same time was when she took urethan.

She continued this medication while in the Catskill Mountains all summer, 1896. Her general condition did not improve; she lost flesh and was pale, though in fairly good spirits most of the time. The amount of albumin in her urine, which was considerable while she was having her attacks, diminished. But while there was hardly a trace and sometimes none in the middle of the summer, there was constantly a small quantity of bile in the urine. In October I saw her. She was in bed, pale (she never was icteric), with anorexia, and a frequent pulse. She improved somewhat until in November she felt better, took drives, and with slight support once walked ten blocks. Then her general condition, however, changed for the worse, without any fever or other tangible symptoms. I saw her with Dr. Dana on December 1st. During that month she grew thinner and paler. On December 28th her nurse noticed some swelling of the abdomen, which had been rather sunk and lean. That swelling was observed plainly by the mother and by Dr. Dana on January 2, 1897. It was considered to be due to obstruction of the bowels; a high enema brought away a peculiar substance, mixed with some blood, of greenish color and offensive odor. The temperature was

but slightly raised, and there was no pain. Within one or two days the abdominal cavity filled up with fluid, the diaphragm was somewhat impeded in its motion, respirations increased to 30 and 36. No anasarca, no local œdema anywhere. The abdominal veins were very numerous and dilated, but there was no caput medusæ.

A few days afterward her (moderate) dyspnœa became a little less annoying; the abdomen appeared a little less tense, and the veins somewhat smaller. Still this apparent temporary improvement did not last, and in a very few days the general condition suggested the necessity of an operation, the beginning of which was to be a laparotomy. Dr. McBurney joined Dr. Dana and me in a consultation. The suddenness of the abdominal effusion suggested the presence of a thrombosis of the portal vein, or the presence of a tumor of some kind, perhaps tuberculous lymph bodies, compressing the portal vein. The spleen had been made out to be large the previous week; the liver appeared somewhat swollen. Some solid or semisolid masses could now and then be felt, but we could not be certain whether we had to deal with normal or inflamed and adherent intestines, or neoplastic growths, or peritonitic exudations. During all this time her strength gave way slowly, with very poor appetite and a urine which, after having been copious, had become scanty and dark. In the last few weeks its specific gravity ranged from 1.025 to 1.033, its urea about 0.031 in 1 c.c. It contained a faint trace of albumin, no sugar, little oxalate of lime, very little bile, a large amount of urates and phosphates, some bladder epithelium, and some little pus and mucus.

Laparotomy was performed by Dr. McBurney on the 10th. There was a gallon or more of a thin yellowish fluid in the abdominal cavity. Its specific gravity was 1.011; it contained but little albumin and few salts. These examinations were made of specimens of fluid which were removed when the discharge was about half finished. The spleen was found to be large, the liver of moderate size; there were no adhesions between the intestines, or between them and the abdominal wall or the viscera. No large neoplasms. The omentum was in good condition, the mesenteric glands were not swollen; the glands surrounding the portal vein were felt to be enlarged, so as to form a thick mass encircling and pressing on the vein.

The surface of the liver was shining and covered with very numerous yellowish-gray bodies. They were of different sizes, from the head of a pin to a bean. Those of the latter size were felt reaching far down into the liver tissue. They were taken to be tuberculous.

Many specimens of the abdominal fluids were centrifuged and stained, and examined for tubercle bacilli or other microbes. One in six such specimens yielded large quantities of bacilli tuberculosis in close proximity to each other.

The general condition of the patient did not improve after the operation. Her temperature was never over 100.8° F. in the axilla, usually 100° or less, down to 98.8° F.; the respiration remained between 30 and 36; her pulse rose until on the day of her death, January 16th, it reached 158, but little influenced by stimulant subcutaneous injections which were continued until about twelve hours before she died.

The autopsy was made on January 17, 1897, twenty-four hours after death, by Dr. James Ewing. The following report is mostly from his pen. By his painstaking investigations extending over many weeks he has placed me under lasting obligations.

Report of Autopsy.—Body that of a moderately well-nourished, distinctly anæmic child. Rigor mortis slight. No œdema or jaundice.

Heart: Pericardium normal. Right chambers moderately distended with clotted blood. Left chambers contracted, nearly empty. Valves, muscle, endocardium normal. No dilatation or hypertrophy.

Lungs show considerable venous congestion and œdema. Bronchial nodes deeply pigmented, not tuberculous. Pleural cavities contain a few drachms of serous fluid.

Peritoneum: Intestinal walls uniformly anæmic; peritoneal coat is slightly dull and in places granular. In pelvic cavity, about drainage tube, are a few drops of pus, and a light purulent coating over adjacent coils of intestine. Parietal peritoneum shows evidences of intense venous congestion, presenting large patches of superficial dark and bloody infiltration. No miliary tubercles are anywhere seen, after close scrutiny.

Liver: Size about normal; surface and section dotted with very numerous light yellow nodules, from pinhead to pea sized, very sharply outlined from the surrounding tissue. Some of these nodules project slightly above the peritoneal surface. They are not caseous, but otherwise closely resemble miliary tubercles. There are many less on the surface than in the interior. The hepatic tissue shows very distinctly the gross appearances of chronic congestion, the centres of the lobules being very deep red and depressed, the peripheries very light colored, but no blood oozes from the sections.

Gall bladder: Contents and mucosa appear normal.

Spleen considerably enlarged, four to five inches long, consistency firm. On section the Malpighian bodies appear very prominently set off from the deeply congested pulp tissue.

Kidneys show moderate venous congestion, but are otherwise normal. Adrenals normal. Pancreas normal. There is marked superficial congestion of ovaries, otherwise the genital organs are normal.

Intestinal mucous membrane appears normal. The solitary follicles are only faintly visible. The stomach is moderately congested and coated with mucus.

On opening the peritoneal cavity attention was at once directed to the condition of the portal vein. The gastro-hepatic omentum was found much thickened and very firm, the enlargement proving on dissection to be due to swelling of the periportal lymph nodes, four or five of which, measuring from five centimetres to one centimetre in diameter, formed a nearly continuous mass along the portal vein. Undoubtedly these nodes during life produced considerable narrowing of the lumen of the vein. On removing the liver and a portion of the diaphragm, an enlarged lymph node, measuring one centimetre by one and one-half centimetres, was found lying immediately above and adherent to the hepatic vein at its junction with the vena cava. It was hard, and its capsule covered with large veins, so as to look almost angiomatous. It did not seem possible that the hepatic vein could have escaped partial compression by this considerable mass of tissue. On section these lymph nodes appeared deeply congested, but were not tuberculous. No thrombi were found in either the portal or hepatic veins. The mesenteric nodes were not enlarged.

Brain rather large, the convolutions not flattened. Pia mater opaque, whitish, thickened, and rather hard over a large surface; moderately congested, mostly so over the region of the motor centres. This change was more perceptible on the left side than on the right. In this neighborhood the convolutions are rather separated from each other and felt hard. This condition was suggestive of interstitial swelling in the white substance. The structure of the brain appeared normal everywhere, the ventricles were empty, the plexuses normal.

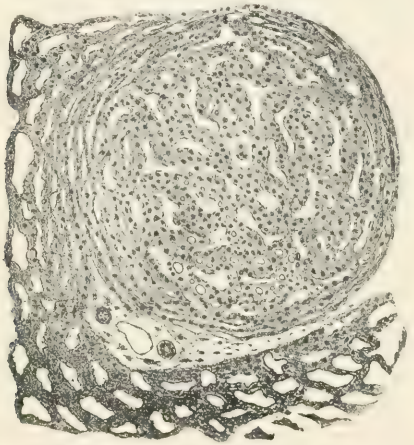
The left half of the cranium was smaller and flatter than the right.

Over the left motor centre there was a defect in the

structure of the bone, one and one-fourth centimetres wide and two and one-fourth centimetres long, in a forward and downward direction. The bone was translucent, its outer surface quite smooth and on a level with the rest of the cranium, its inner surface depressed. This depression was quite sharp, as in craniotabic defects. There were two more such defects on the same left side, in a forward direction, quite as wide but shorter, about three centimetres from the median line. One more such spot was found over the left brow; another was located over the left motor centre, one and one-half centimetres long and one and one-half centimetres wide. The space of the large fontanelle, two and one-half by three centimetres, was occupied by hard, thick, and rather irregular bone, which was surrounded by a narrow (about three-fourth centimetre) semitransparent area. To the left of this, and rather forward and adjoining the coronal suture, was a triangular osseous island, also flanked by a transparent area.

The impressiones digitatæ and Pacchionian depressions were more pronounced on the left side.

On the occiput, where a trauma was sustained five years previously, no abnormal condition was observed.



The pia was moderately congested, and over the whole convexity was considerably thickened and opaque. The brain tissues appeared normal. The thickness of the parietal bones varied greatly, especially along the sagittal suture.

Microscopical Examination.—The liver shows the usual lesions of advanced chronic congestion, with complete atrophy of cells at the centres of lobules, and slight fatty degeneration of cells at the peripheries of lobules.

The small nodules above described prove to be miliary adenomata. They are composed of thick cords of hypertrophic liver cells, usually containing more than one nucleus, and at some points showing considerable fatty infiltration. The larger adenomata are surrounded by a distinct fibrous capsule, within which effects of chronic congestion have not been felt, as the capillaries of the adenomata are not at all widened.[1] The cords of liver cells surrounding the nodules are much compressed for a considerable distance (see figure).

The lesions in the lymph nodes include:

1. A chronic inflammatory hyperplasia, with the production of new connective tissue, extensive exfoliation of endothelial cells, and atrophy of lymphoid cells.

2. An extreme dilatation of veins and capillaries, both within and without the nodes.

The inflammatory process has replaced considerable portions of the nodes by a tissue apparently composed of flattened and fusiform endothelial or connective cells, and entirely lacking in lymphoid cells. In these areas the capillaries are often dilated and gorged with blood. The lymph nodules are all quite small, and many appear to have been replaced by the above tissue. There is a slight deposit of anthracotic pigment in the fibrous tissue. The large neighboring veins are enormously dilated, and possibly increased in number, so as to give an appearance not unlike that of a cavernous angioma. The venous stasis has likewise affected the vessels within the nodes, the medullary lymph cords being entirely absent and replaced by dilated blood spaces or fibrous tissue. The condition of the lypmh nodes indicates a process of older date than that of the changes in the liver.

The mesentery shows œdematous infiltration, and about some small vessels are collections of mononuclear and polynuclear cells.

The spleen shows the effects of chronic congestion equally marked with those of the liver. The sinuses are much dilated, and the pulp cells contain a large deposit of blood pigment.

The intestinal wall shows a light coating of fibrin with exfoliation of endothelial cells.

The ovaries and Fallopian tubes show venous congestion, but no other lesion.

Brain: The motor cortex of both sides was cut in thin slices and hardened in saturated watery solution of corrosive sublimate.

Sections stained by Nissl's method gave very unsatisfactory results, owing to advanced post-mortem changes. As nearly as could be judged, the motor areas of both sides were identical in appearances, including the numbers and configuration of the cells, and the character of chromatophilic bodies and intracellular network. The pia of both sides was considerably thickened, that over the left motor area very much so.

Some capillaries were found containing colonies of cocci.

The ganglion cells of the cranial nerve nuclei (XII., X., IX. examined) showed no unusual appearances by Nissl's stain.

Bacteriological Examination.—A portion of one of the superficial adenomata, including a section of the capsule of the liver, was inserted beneath the skin of a guinea-pig. Seven weeks later no inflammatory changes were to be found at the point of inoculation or in the adjoining lymph nodes.

A similar negative result followed the inoculation of another guinea-pig with a swab from the fluid and pus in the bottom of the drainage tube. The fluid in the drainage tube, smeared on cover glasses, showed the presence of numerous cocci in masses and short chains. Pure cultures of staphylococcus pyogenes aureus and of streptococcus pyogenes, of marked virulence, were secured by Dr. Charles Norris from this same fluid.

The fluid from the drainage tube and sections of the intestinal wall, mesentery, liver, spleen, and lymph nodes were stained for tubercle bacilli with a negative result.

The serosa of the inflamed intestines contained cocci in moderate numbers.

The spleen contained large numbers of minute colonies of cocci, and in the motor cerebral cortex and in a lymph node single colonies of cocci were observed.

Diagnosis.—Chronic inflammatory hyperplasia of

[1] In this respect our specimen differs from the majority of the few cases which have been described. In them the liver-cells were thoroughly compressed and destroyed by copious interstitial tissue, and new cells were developed through a compensatory process.

periportal and perihepatic lymph nodes, of undetermined origin. Partial compression of hepatic and portal veins. Chronic congestion of liver and portal viscera. Multiple miliary adenomata of liver. Ascites. Peritonitis. Tubercle bacilli in the fluid. Septicæmia.

Epicritical.—From the pathological standpoint the obscure feature of the case is the relation of the swelling of the perihepatic lymph nodes and the condition of the liver. In the absence of any other adequate cause it is necessary to conclude that the advanced chronic congestion of the liver was due to a compression of the hepatic vein from the enlarged lymph node lying above and upon this vein. It then becomes necessary to discover a cause of this hyperplasia of the lymph nodes, which, with the periportal nodes, were the only ones in the body thus affected. Several possibilities may be suggested. It is possible that the lymph nodes were subjected to chronic irritation from intestinal toxæmia, in which case it is difficult to see how the mesenteric nodes could have escaped, as they did, a similar irritation and hyperplasia. The probability of a serious retrograde irritation from the thoracic chains must be regarded with caution, since the thoracic nodes were not enlarged, and the bronchial nodes showed only moderate pigmentation. The deposit of pigment in the perihepatic node was very slight and apparently quite insufficient to induce the lesion found in the node. Nevertheless such a possibility may be entertained.

Cholecystitis could have affected the periportal nodes, and suppurative lesions in this viscus commonly do so; but there were no evidences, either gross or microscopical, of any disease of the gall bladder. The considerable size of some of the adenomata (one-half centimetre in diameter) suggests that these may have been the primary lesions, and that the disordered condition of the hepatic circulation and function led to the hyperplasia of the lymph nodes draining the organ. While there is no positive evidence on which to deny such a course of events, many recent studies of nodular hyperplasia of the liver tend to show that this lesion usually represents a regenerative tendency, well marked in liver cells, to replace disordered or destroyed hepatic tissue by way of compensation. No other cause for liver congestion can be found in our case in heart, pleura, or lungs. Some extensive studies of this character have been contributed, as follows:

Flock: "Ueber Hypertrophie und Neubildung der Lebersubstanz," *Deutsches Archiv für klinische Medicin*, 1895, Bd. lv.

Marchand: "Ueber Ausgang der acuten Leberatrophie in multiple knotige Hyperplasie," Ziegler's *Beiträge*, 1895, Bd. xvii., p. 206.

Meder: "Ueber acute Leberatrophie mit besonderer Berücksichtigung der dabei beobachteten Regenerationserscheinungen," Ziegler's *Beiträge*, 1895, Bd. xvii., p. 143.

Therese: "Des adenomes du foie," *L'Union Médicale*, 1895, No. 34.

Babes et Manicatide: "Les proliférations des cellules hépatiques dans les differents affections du foie," Ref. in *Centralblatt für Pathologie*, etc., 1896, No. 23.

The very general distribution of the nodules in the present case, and the fact that they represented areas of apparently normal liver cells—in the diagram the presence and absence of these cells in adjoining territory is beautifully represented—in which the effects of the chronic congestion were not at all noticeable, seems to support strongly the view that these miliary adenomata were entirely the result of the advanced chronic congestion and atrophy of liver cells which affected the entire organ.

As already stated, moreover, the lesion in the lymph nodes appears to have been probably of older date than the adenomata of the liver.

Pressure on the hepatic vein having been once established, thereby obstructing the venous return from the nodes themselves, it is readily seen how the course of events should lead to exactly the condition found at autopsy.

The peritonitis and septicæmia which terminated the case may properly be regarded as the natural and very frequent result of the sudden relief of pressure from the abdominal viscera, especially the intestines, allowing the passage of intestinal bacteria into the peritoneum, and apparently also into the general circulation. The intestinal lumen contained a very abundant growth of cocci: the streptococcus and staphylococcus were isolated from the peritoneum, and bacterial thrombi composed of cocci were found in the spleen abundantly, and in the brain and lymph nodes.

This consideration affords also a clew to the presence of tubercle bacilli in the serum contained in the abdominal cavity. They are transferred through the circulation, either of the blood or of the lymph. The latter would start from lymph nodes which were, however, nowhere affected, nor was there any organ or tissue infected with tuberculosis. Therefore the presence of tubercle bacilli can be explained by transmission through the blood current only. Evidently they were only a complication, an incident. When the rapid effusion took place from the blood-vessels of the peritoneum and the intestine, where the bacilli happened to be located, without having given rise to local or general symptoms, the vessels were emptied of a thin serum—of 1.011 specific gravity—with all its contents. The alkaline fluid in the abdominal cavity proved an excellent nutrient and a preservative for the bacilli.

The presence of bacilli in the ascitic fluid, in the absence as well of tuberculous deposits or degenerations anywhere as of lesions in the intestine which could be charged with admitting the microbes into the circulation, is no longer an improbability, since it has been proven that surface lesions of a mucous membrane are not required to admit tuberculosis, nor hiatuses in the epithelial covering, which, for instance, are possessed by the tonsils (Stoehr) in their normal state. It has been known for some time that initial lesions in the lungs, for instance, need not correspond with the localities of original affections, for pulmonary infiltrations will follow the subcutaneous injections of bacilli in distant places. Koch proved that lymph bodies may become diseased without affections of their roots. Solid particles are known to penetrate the lungs. The spores of saprophytes and of anthrax are so admitted. Whether this happens more readily in children, whose organs are less changed by the solid results of previous morbid processes, remains to be seen. Bollinger and Heller demonstrated that tubercle virus may penetrate through intact tissue, and that it is not necessary to assume, with Babes, that cocci prepared the soil for absorption. The tubercle bacilli in the ascites of our case would, therefore, be explained in one of two ways. They were, before entering the abdominal cavity, contained either in the circulating blood or in the intestinal tract. The former is very improbable, for there were no miliary deposits anywhere. The presence of bacilli in the intestinal tract is explained by the facility of their admission in food. It is probable that there are but few intestinal tracts but are harboring bacilli now and then. It is under favorable circumstances only that they are absorbed instead of being expelled. Such favorable circumstances are either the presence of local lesions or sudden changes of osmosis. The latter existed in our case.

The local cranial defects remain unexplained. If

they had been found in the skull of a baby less than six or ten months old, they would certainly have been claimed as rachitical. Craniotabes, however, when the rachitis has disappeared, never leaves behind it these attenuated circumscribed spots. There was no symptom of rachitis in the patient when an infant, except constipation. There was, moreover, no tumor, no thickening inside to explain a local absorption of such circumscribed character. I prefer to point to this instance of defective local bone development on some other than rachitical basis.

It has been noticed that the pia and the surface of the brain exhibited marked alterations from the normal, but none so localized as to explain the spasmodic symptoms constituting the very picture of what we mean by the term Jacksonian epilepsy. The advisability of an operation undertaken to find and remove its local cause was often considered by the medical men who studied the case. It never was urged by any one, it was advised against by some. Nothing that is positive can be learned by this feature of the case, except the necessity of care and caution and prudence.

A therapeutical remark will not be out of place. It has been seen that the bromides would sometimes be required in such quantities as to interfere seriously with the general health of the patient. When the doses of urethan, recommended by Dr. Dana, were given persistently, the convulsive attacks ceased very soon, never to return, and there were no disagreeable symptoms attributable to the remedy.

FELONS AS MEDICAL PRACTITIONERS IN NEW YORK.

By W. A. PURRINGTON, Esq.,

NEW YORK.

In 1887, after three years of effort, conflicting views and interests were sufficiently harmonized to secure the enactment in New York of chapter 647 of the laws of that year, which is substantially the present medical law of this State.[1] Section 6 of that act introduced this new provision into the law: "No person shall be licensed or permitted to practise physic or surgery in this State who has been convicted of a felony by any court of competent jurisdiction; and if any person who is or hereafter shall be duly licensed to practise physic or surgery in this State, shall be convicted of a felony, as aforesaid, his or her license to so practise, if any, shall be revoked by the fact of such conviction having been had. Any person . . . who, after conviction of a felony, as aforesaid, shall attempt to practise physic or surgery in this State, . . . shall be deemed guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not less than $250, or imprisonment for six months for the first offence, and upon conviction of a subsequent offence, by a fine of not less than $500 or imprisonment for not less than one year, or by both fine and imprisonment."

Minimum punishments established for the unlawful practice of medicine by others than felons were a fine of $50 for the first offence, and one of $100 or imprisonment or both for the second; the maximum fine for either offence being the ordinary maximum in cases of misdemeanor, viz., $500. Thus while a convicted felon could not be punished by a greater maximum fine than any other illegal practitioner, the offences of both being misdemeanors, neither could he, on the other hand, receive so light a sentence as he might except for such previous conviction.

[1] For a review of medical legislation in the State of New York, prior to 1887 see the MEDICAL RECORD of October 23, 1886, vol. 30, No. 17.

When the bill came before the governor he favored its general purpose, but suggested that this new provision might work hardship in individual cases; instancing a medical practitioner recently pardoned by himself—an unfortunate illustration, as the event has proved, for the man has been again convicted of felony.

The brief then submitted in behalf of the State and county medical societies, in arguing the constitutionality of the law, cited the test-oath cases in the United States supreme court, and said: "Both the prevailing and dissenting opinions hold that any proper qualifications may be required of professional men, that do not constitute a penalty for an act not so punishable when committed." And in enumerating the classes which would benefit by a veto, the brief mentioned as one of them "convicted felons, who, as in the case of one now in New York, may serve as many as three terms of imprisonment for criminal malpractice and return to 'renew business at the old stand.'"

By chapter 661 of the laws of 1893 the commissioners of statutory revision, one of whom had been consulted upon and was familiar with said enactment, codified the laws relating to public health into chapter 25 of the general laws, which re-enacted the provision in question, by these words in section 140: "Nor shall any person practise medicine who has ever been convicted of a felony by any court," and these words in section 153: "Any person . . . who, after conviction of a felony, shall attempt to practise medicine, . . . shall be guilty of a misdemeanor, and on conviction thereof shall be punished by a fine of not less than $250, or imprisonment for six months for the first offence, and on conviction of a subsequent offence, by a fine of not less than $500, or imprisonment for not less than one year, or by both fine and imprisonment."

This codification, however, while forbidding medical practice to the unlicensed and unregistered citizen, provided therefor neither fine nor imprisonment, but only a civil penalty. Whether this omission, specifically to inflict the fine theretofore imposed by the laws codified, removed ordinary illegal practice from the class of misdemeanors, was a question on which opinions differed; but it was never submitted to the courts nor need it be discussed here, for, whether it did or not, the convicted felon still remained liable to a greater minimum punishment than non-convicts in *pari delictu*.

By chapter 398 of the laws of 1895, section 153 of said codification was so amended as to provide that "any person who, not being then lawfully authorized to practise medicine within this State and so registered according to law, shall practise medicine within this State without lawful registration or in violation of any provision of this article; and any person who, . . . after conviction of a felony, shall attempt to practise medicine, or shall so practise, . . . shall be guilty of a misdemeanor, and on conviction thereof shall be punished by a fine of not more than two hundred and fifty dollars, or imprisonment for six months for the first offence, and on conviction of any subsequent offence, by a fine of not more than five hundred dollars, or imprisonment for not less than one year, or by both fine and imprisonment."

Thus this amendment of 1895, which is the existing law as to penalties, by its new provisions punishes all illegal practitioners alike, whether felons or merely non-licentiates, by a fine which cannot exceed for the first offence $250, or half the maximum fine imposed on misdemeanants by the penal code and theretofore by the various medical laws codified.

Such being the law in 1896, Benjamin Hawker, alias Perry, alias West, was tried under it upon an indictment setting forth, as reported, only two facts: (1) that he had been convicted in 1878 of the crime of

abortion, and sentenced to ten years in the penitentiary; (2) that he afterward unlawfully practised medicine in the city of New York upon a certain woman on the 22d day of February, 1896, against the form of the statute, etc.

To this indictment defendant demurred, upon the ground that these facts did not constitute a crime; contending that the statute was only prospective, or, if retrospective, then, as to him, unconstitutional, in that his conviction of felony, having been had prior to its taking effect, the law was *ex post facto*, as creating a new penalty for an offence for which he had been already punished.

The demurrer was overruled and defendant thereafter convicted and sentenced upon his admission of the truth of the facts pleaded. On appeal the appellate division, by a divided court, sustained his contention; the prevailing opinion holding that the law as applied to the case of a physician convicted of felony before it took effect is *ex post facto*, and therefore unconstitutional, in that it does provide a new penalty for his crime by depriving him of his license to practise medicine, which is in the nature of a property right, not forfeited by a conviction of felony prior to the time this law took effect.

The opinions of the court [1] are noteworthy expositions of much argued topics, and deserve quotation at length.

Upon the point of legislative power to require good moral character as a preliminary qualification for admission to medical practice, the prevailing opinion laid down the premise that such a test must relate to present status, and must not debar a wicked man, turned away from his wickedness committed prior to the law's enactment, from practising medicine in a lawful and right fashion. Said the court,[2] the italics being ours:

"Assuming for the purposes of the argument that the legislature may require, *for the continuance in the practice of medicine*, that the practitioner shall possess professional knowledge and skill and also *good moral character*, it is obvious that *such requirement must relate to a present status or condition of a person coming within the terms of the act.* The law under which this appellant was indicted does not deal *with his present moral character.* It seizes upon a past offence and makes that, and that alone, the substantial ingredient of a new crime, and the conviction of it years ago the conclusive evidence of that new crime." And later:[3] "The design of the act is, therefore, fully apparent. No matter how praiseworthy the motive may be, *it is meant to deprive one class of persons, otherwise lawfully engaged in the exercise of a right, of that right because of past occurrences, 'many of which are in no wise associated with their professional pursuits,'* for this act strikes at the unfortunate man who in his youth may have violated the law, and, without real evil intent, have committed and been convicted of any felony and pardoned the very day of his conviction, as well as the hardened criminal, guilty of as foul an offence as that of which this appellant was convicted. The underlying purpose of the act may be to purge the medical profession of members unworthy of confidence, but the real effect is to accomplish that by inflicting an additional punishment through a newly created offence inseparably connected with the anterior crime, and thus bring about a result the constitution forbids, no matter in what form the statute is drawn."

Upon the point of Hawker's status at the time of his conviction of felony in 1878, and the ineffectiveness of that conviction to deprive him of his "right" to practise medicine, the court said:[4]

"*He had absolutely the right to practise medicine the day before the statute was passed.* His former conviction entailed the punishment of imprisonment and disfranchisement as a voter, but *it did not take away from him his property in the right to earn his living on the expiration of his imprisonment by engaging in the profession of which he was and is a member.* His civil rights were not extinguished, but only suspended, during his imprisonment (2 R. S. 701, § 19; Penal code, § 710). *That his right to so engage in that profession is in the nature of a property right cannot be disputed. It is not a mere revocable license.* As is said in the *Dent* case (*supra*),[1] in this country 'all vocations are open to every one on like conditions. All may be pursued as sources of livelihood, some requiring years of study and great learning for their successful prosecution. The interest, or, as it is sometimes termed, the estate acquired in them, *that is, the right to continue their prosecution, is often of* great value to the possessors *and cannot be arbitrarily taken from them any more than their real or personal property* can be thus taken.' That means that if it is taken away it must be for cause."

Of the five justices sitting at the argument, three concurred in this prevailing opinion and judgment was reversed.

The fifth justice dissented, upon the ground that the exclusion of felons from practice by the act was not the infliction of a new penalty for an old offence, but merely the establishment of a test of moral fitness for the practice of medicine, not in itself more arbitrary than the test of general qualification to practise held constitutional in the Dent case, viz., that continuous medical practice within the State for ten years prior to March 8, 1881, should be equivalent as evidence of qualification to a diploma or certificate of successful examination before the board of health.

There is, however, a distinction here that the learned justice did not comment upon; for while it is quite true that to accept any term of practice within the State as a test of qualification to continue so to practise is arbitrary, and conceivably absurd, yet such continuous practice was not the *sole* test under the West Virginia statute, which permitted any one to acquire a right either to begin or continue to practise by showing his qualifications through examination or by diploma; while under our health law the felon is absolutely barred from practice.

The dissenting justice was also of opinion that in pointing out the hardship conceivably resulting to a convict of present moral life, the prevailing opinion rather criticised the propriety of the legislative test than adduced a reason for declaring it unconstitutional; and he might well have pointed out also that it is not more severe to debar a person from practice for a past felony than it is to close the door of hope and leave no *locus pœnitentiæ* for future offenders; as to whom the prevailing opinion admits that the law is constitutional.

Finally, the dissenting justice, like his colleagues, also assumes that Hawker was at the time of his conviction in 1878 a licensed physician, and therefore says,[2] after reciting the right of the State to make necessary health regulations: "I do not understand that they" (such regulations) "are necessarily *ex post facto*, because rights of the individual that existed prior to the passage of the law that creates the restriction are curtailed. I suppose that if an act was passed requiring that those having a contagious or infectious disease should be isolated so as to avoid communicating

[1] Dent *vs.* West Virginia, 129 U. S. 114, holding constitutional a statute establishing, as one test of fitness to practise, the fact that the licentiate had practised medicine within the State of West Virginia "continuously for the period of ten years prior to the 8th day of March, 1881," and affirming the conviction of one who had practised in the State for only five years.
[2] At p. 194.

the disease, the fact that such disease existed prior to the time of the passage of the act would not make the act *ex post facto*, and so unconstitutional, nor would such isolation or control over a person who has such a disease be a punishment for having the disease:" etc. To which the answer would seem to be that a man is isolated because he has the disease, not because he has had it—the argument of the prevailing opinion on this point only being that a previous conviction of felony is not more conclusive proof of a present immoral character, than the scar of small-pox is a sure indication of a present contagion.

Thus it appears that all the judges of the appellate division assumed, and were entitled upon the briefs of counsel to assume, in their premises, as a fact of record, that in 1878 Hawker had a right to practise medicine, and upon that assumption their reasoning is based.

And their conclusions are,[1] the italics being their own: "*First*, that the provision we have considered of the public health law *is constitutional* so far as it operates prospectively and upon persons convicted of felony after its passage. *Second*, that it *is unconstitutional* in as far as it applies by its terms to persons so convicted before the law went into operation."

But the court of appeals has now reversed the appellate division's judgment and affirmed the judgment of conviction, upon the sole point, apparently, that, *so far as the record shows*, Hawker never was a physician, and therefore was not deprived by the statute of a right to practise medicine—a point that does not appear to have been raised at all by the briefs of counsel.

The prevailing opinion in the court of appeals,[2] where also there is dissent, holds that the statute is clearly retrospective, and admits that, if it enhanced defendant's punishment for his felony committed prior to its enactment, it would be as to him unconstitutional.

But it goes on to say,[3] the italics again being ours: "It is not contended that the law in question makes any change with reference to the felony of which the defendant was convicted, *or that there has been any aggravation or change, with reference to the punishment provided therefor. What has been done is the creation of a new offense, a misdemeanor after a felony dependent upon acts thereafter committed in violation of the statute* and providing a punishment for such misdemeanor. It is in the nature of providing punishment for a second or an additional offense, and it is claimed, with reference thereto, that it operates to deprive the defendant of his rights of property, of his right to earn a living by the practice of medicine, and that, by being deprived of this right, the effect is to aggravate his punishment for the felony. *The difficulty, however, with this contention is, that it does not appear from the record in this case that he ever had any right to practise the profession of medicine, and that no presumption can be indulged in to that effect.* . . . It does not now appear that he ever studied medicine a day in his life; that he ever received a diploma from any medical college or university; that he was ever registered or licensed to practise medicine, or that he ever did practise before the 22d day of February, 1896, the day of the charge upon which the indictment in this case was founded. So that there is an entire absence of any evidence showing, or tending to show, that he was deprived of any rights of property, or of means of earning a livelihood, that he theretofore enjoyed and possessed."

And after asserting the legislative power to require good moral character as a test of fitness to practise medicine, the opinion concludes thus, the italics once more being ours:[4] "If, therefore, the legislature may impose conditions upon which persons of good moral character shall engage in the practice of medicine, and may impose a punishment for all persons violating the conditions, it appears to us that the legislature may also prohibit from practising a person who has been convicted of a felony, whose character is presumed to be bad, *who has never before studied or practised medicine, and who has not conformed to a single condition or requirement of the statute under which other persons are licensed to practise.* The defendant has been deprived of no rights secured to him either by the United States or State constitutions."

As there is no dispute that the statute can and does prohibit from practising a person who has never studied medicine, regardless of whether he is a felon or a Christian gentleman, this opinion would be clearer if the italicized words last quoted were omitted. They only cloud, if they do not evade, the question sought to be raised, the statement of which is simple enough. —Can the legislature, under its admitted power to provide a test of the moral fitness of licentiates in medicine, exclude by a general law all convicted felons from the ranks of the medical profession?

Only two out of the seven judges of the court of appeals seem to have concurred in the reasoning of its opinion; for two concurred[1] "*in result solely on the ground that the record contains no evidence that the defendant at the time of his conviction, or at any other time, was a physician;*" from which it is to be inferred that they approved the reasoning of the prevailing opinion of the appellate division, and would have voted to sustain its conclusion had Hawker appeared by the record to have been, when convicted in 1878, a licensed physician. The remaining two judges dissented and voted to affirm the judgment appealed from, showing that in their minds the conviction could not be sustained merely because of the record's failure to show that the defendant was ever a licensed practitioner, but must depend solely upon the allegations and proof, viz., that defendant after conviction of felony in 1878 practised medicine in 1896; that the illegality of the practice under the allegation was due solely to the former conviction of felony and not to the failure to prove a license and that in so far as the law made such previous conviction an element of the offence it was, in their opinion, *ex post facto*, regardless of whether Hawker was a physician in 1878 or not.

The conclusions from all this seem to be:

(1) The final judgment against Hawker is a chance result due to an explicable oversight in making the record—an oversight scarcely to be criticised or wondered at, since it seems to have escaped the observation of all the able counsel in the case, for defendant as well as for the prosecution, of the careful trial judge as well as of the learned justices of the appellate division. The point upon which the court of appeals decides the case is, as already said, one not raised by counsel; nor could it have been fairly raised by the prosecution, which evinced no desire to take any advantage of it; just as in the Dent case counsel waived technical defects in the record in order that the highest court might pass upon the substantial question sought to be raised. The oversight, as already indicated, is this: That the indictment merely alleges two facts: (*a*) The conviction of Hawker, in 1878; and (*b*) that afterward "he unlawfully did practise medicine," etc. The intent of the prosecution was, of course, to test the question whether any *person* convicted of felony might thereafter practise medicine. But unfortunately the indictment's allegation that Hawker unlawfully practised medicine contrary to the form of the statute, has been held to be a good pleading of the ordinary misdemeanor of unlicensed practice, quite apart from any question of felony, and de-

fendant failed to prove by way of defence to this charge the fact that in 1884 he registered in the county of New York, under a diploma of the Eclectic College of that city, alleged to have been conferred upon him in 1876, prior to his said conviction. If he had proved that this diploma had been conferred upon him, the reason for the reversal by the court of appeals would not and the facts assumed by the appellate division would have existed, and the question whether the law is constitutional in so far as it debars from continuance in practice physicians convicted prior to its enactment would have been decided. But the question would still have remained, whether the law is constitutional in so far as it forbids a layman convicted of felony prior to its passage from acquiring a medical license under the same conditions imposed upon other laymen not so convicted.

(2) The question sought to be decided would seem to be still open; neither opinion of the appellate division being, in the view of the court of appeals, a strictly binding authority; since each assumes a state of facts not before the court.

(3) But if, technically speaking, no absolute and final decision has been rendered upon the point sought to be raised, nevertheless the preponderance of judicial opinion, both in the appellate division and in the court of appeals, is that the medical act is unconstitutional in so far as it expelled from practice licensed physicians on account of their convictions of felony before it took effect. On this point the judges stand four to one in the appellate division, and, at least, four to three if they are not unanimous in the court of appeals; so that, should Hawker again be arraigned, he, probably, would make a successful defence if he could establish the validity of the eclectic college's diploma. And a very able and learned judge, sitting in oyer and terminer in 1884, held that a diploma from that college was a defence to a charge of unlicensed practice, even if purchased *in absentia* from the officers empowered to bestow it, and that, too, although two signatures upon it were proved by uncontradicted testimony to have been forged or procured by a false pretence; a decision from which the prosecution had no appeal.

It is to be hoped, therefore, that the questions involved may be brought up again upon a record adequate to present them fully.

So far as the previous conviction of felony is an element in the case, the dissenting judges of the court of appeals seem to hold that it makes no difference whether Hawker when first convicted was a physician or a layman. If the law is unconstitutional as depriving a physician of his "right" or "quasi right" to practise medicine, then by parity of reasoning it would seem equally unconstitutional in debarring a layman from his privilege *to acquire that right* upon the same terms with others; for if the law operates only on present status, speaking from the time of its enactment, and if prior conviction of felony does not establish that status, then Hawker or any one in *pari delictu*, even assuming that he had not the right to practise medicine in 1878, had at least the right to acquire it on the same terms with others; if not, then his punishment for felony was enhanced quite as much by his prohibition from entering the ranks of physicians as by his expulsion from them. Or to put it interrogatively, can the Regents to-day refuse a license to A, otherwise qualified, solely because in 1886, while a layman he was convicted of a felony? Again, let us suppose the case of one convicted of felony before the act of 1874 restored the penalties for unlicensed medical practice, which had been abolished by the act of 1844, and therefore at a time when, as was said in Bailey *vs.* Mogg,[1] quackery might certainly "boast of its triumphant and complete establishment by law," and every one had the so-called "right" to practise medicine—a right not created but only regulated by statute.[1] Does it not follow logically, from the reasoning of the majority of the appellate division and of the dissenting judges of the court of appeals, that as all felons at large had a right then to practise medicine, our supposed convict could not be debarred on account of his past crime from continuing to exercise that right, if in other respects he could show statutory qualifications? In considering these questions and the effect upon them of the prevailing opinion of the appellate division, we must remember that, although its argument proceeded upon the assumption that Hawker was a physician when first convicted, its conclusion above quoted is that the law is "unconstitutional in so far as it applies by its terms to *persons* so convicted," etc., which strictly means all persons—physicians and laymen.

It will be remembered, too, that that opinion, following the Dent case, laid much stress upon the fact that convictions of felonies "*in no wise associated with their professional pursuits*" would serve under the statute to forfeit licenses of physicians. Are we to infer that if the provision of law in question had affected only physicians convicted of abortions or of manslaughter by reckless administration of poison to patients, etc., it would be constitutional in its retroactive phase, while it is now unconstitutional because it prohibits medical practice to one convicted of burglary or larceny from the person?

There are many arguments that suggest themselves in the premises, which there is here no space even to mention. The construction of laws applying the police powers of government to the regulation of the various professions and trades is one of the most difficult functions of the judiciary. The facts are kaleidoscopic. That opinions differ is not surprising; the opinions of the same judge may undergo change even upon the same state of facts, and may appear to change with varying facts. What is needed in this, as in every case, is an authoritative decision upon a record adequately presenting the facts. Then, and then only, we may know accurately where we stand before the law. Meantime we may profit very much from the very able and learned discussion by both court and counsel of a puzzling question of the constitutional limits of the police power in regulating the licensing of physicians.

THE MICROBE OF YELLOW FEVER.[1]

BY GIUSEPPE SANARELLI, M.D.,

DIRECTOR OF THE INSTITUTE OF EXPERIMENTAL HYGIENE [illegible] OF MONTEVIDEO.

Four centuries have passed since a terrible disease, until then unknown, attacked the daring men who accompanied Columbus in the discovery of America. Two centuries scarcely have gone by since the same disease, leaving its natural habitat in the Gulf of Mexico and the Antilles, appeared first in South America and gave the Portuguese physician, Ferreira da Rosa, the opportunity to describe that strange morbid process which was to acquire so sad a celebrity under the name of yellow fever.

While other infectious diseases, since the great epidemics noted in history, whether through a sort of acquired immunity, transmitted by heredity or owing

[1] Wert *v.* Clutter, 37 Ohio St. 348.

[1] A translation by A. C. H. Russell, M.D., Surgeon, U. S. Navy, of a public address delivered June 10, 1897, in the Solis Theater, Montevideo. The author's description of the symptoms and morbid anatomy of yellow fever in man, and portions of his account of the symptoms and post-mortem examinations in animals experimented upon, have been omitted.

to scientific prophylaxis, seem to have diminished, little by little, in virulence, or at least tend to remain in their original limits, yellow fever, on the contrary, has progressively enlarged its domain, and is far from even diminishing its virulence.

From the point of view of the anatomical lesions, yellow fever may be considered as the type of the diseases (steatogenous) that cause fatty degeneration, since, although congestive and hemorrhagic phenomena predominate in the symptoms, degenerative lesions present themselves first in the anatomical changes.

There does not exist, however, any lesion truly pathognomonic of yellow fever, although the changes of yellow fever in their entirety constitute, as Jaccoud has said, "an anatomical criterion more clear and better defined than that of the majority of infectious diseases."

I procured the material for my studies partly at the Lazaretto of the Island of Flores, the quarantine station of Montevideo, where a small laboratory was set up last summer, and partly in the hospital of San Sebastian at Rio.

When I thought of devoting myself to the study of yellow fever, Sternberg and also the majority of the medical men of Brazil thought they had to deal probably with a local infection, seated principally in the stomach. In that organ, according to them, the infectious agent, as yet unknown, elaborated a toxic substance, which, absorbed into the blood, gave rise to the general symptoms characteristic of yellow fever.

The recognition and the isolation of the specific agent of yellow fever must be considered as the most difficult undertaking yet presented to the patient investigation of bacteriologists.

The cadavers of the victims of yellow fever are either sterile or they are found to be invaded throughout by certain species of microbes, as the streptococcus, the staphylococcus pyogenes, the coli bacillus, the proteus, etc., which cannot be considered as the cause of the disease; in a word, they show a mixture of microbes, the isolation and the classification of which require a total of work which makes systematic and careful investigation impossible.

I owe the chance of the discovery of the microbe of yellow fever to the second case of the disease which presented itself to me at the Island of Flores. This case, though it showed a mixture of various microbes, had, in a state of relative purity, the specific microbe, to which I have given provisionally the name of "bacillus icteroides," because yellow fever is known also under the name of typhus icteroides.

I have said, "in a state of relative purity," because yellow fever is the prototype of the diseases of mixed infection. I have never found the "bacillus icteroides" alone in the autopsies I have made. It has been associated always with the micro-organisms previously referred to or among the numerous species of common microbes, or it has been impossible to find it because the other microbes, having entered the organism in its train, have ended by impeding its evolution and have even caused it to disappear entirely.

The "bacillus icteroides" must be sought for in the blood and in the tissues, and not in the gastro-intestinal tube, in which, contrary to what might have been supposed *a priori*, I have never encountered it.

In reality, in yellow fever, as in typhoid fever, there takes place in the digestive tube an extraordinary multiplication of the coli bacillus, which is found there in a state of almost absolute purity.

Upon the result of my investigations I will say that the isolation of the specific microbe of yellow fever is possible in only fifty-eight per cent. of the cases.

The reasons for this are easy to understand. Before all, in the beginning of the disease, the "bacillus icteroides" multiplies very little in the human organism, a very small quantity of its toxin being sufficient to provoke in man the worst type of the disease.

In the second place, the toxin, whether by itself or indirectly through the profound lesions it causes, especially in the digestive mucous membrane and in the liver, facilitates in an extraordinary manner every sort of secondary infection.

According to my investigations, the "bacillus icteroides" is found in the circulating blood and in the tissues: the germ of yellow fever does not reside in the digestive tube, and its poison, instead of being absorbed through the intestinal walls, is fabricated in the interior of the organs and in the blood.

Morphologically this bacillus does not present at first sight anything characteristic. It is a little rod, with rounded extremities, united at best by pairs in cultures and in groups in the tissues, from two to four micromillimetres in length, and generally two or three times longer than it is broad. It is sufficiently polymorphous.

Investigating it in the tissues does not give good results, unless the death of the patient occurs without secondary septicæmia.

Even in the cases that give the best results from the bacteriological examination, it is not easy to place the bacillus in evidence in sections of the tissues, on account of its extremely small number. In spite of this, by using the utmost care, one can find it in the organs, united usually in small groups and situated always in the minute capillaries of the liver, the kidneys, etc.

The best way to demonstrate not only its presence but also its special tendency to arrange itself in small groups, preferably in the blood capillaries, consists in placing in the incubator, at 37° C. for twelve hours, a fragment of the liver taken from a fresh cadaver in order to favor the multiplication of the specific microbe. The yellow-fever bacillus grows sufficiently well in all the ordinary culture media. In common gelatin it forms rounded colonies, transparent and granular, which during the first three or four days present an aspect analogous to that of leucocytes.

The granulation of the colony becomes more and more pronounced, appearing ordinarily as a nucleus, central or peripheral, completely opaque; in time the whole colony grows entirely opaque. It never liquefies gelatin.

In beef bouillon the bacillus grows quickly, without forming either pellicles or deposits.

On blood serum solidified it grows in a manner almost imperceptible.

Cultures on agar-agar represent for the "bacillus icteroides" a means of diagnosis of the first order; but the demonstration by this means of diagnosis is efficacious only under certain determined conditions.

When the colonies grow in the incubator, they present an appearance that does not differ from that of the majority of the other species of microbes: they are rounded, of a slightly iridescent gray color, transparent, even in surface, and regular in outline.

If, instead of causing the colonies to grow in the incubator at a temperature of 37° C., they are allowed to evolve at a temperature of from 20°–22° C., they appear like drops of milk, opaque, projecting, and with pearly reflections: that is to say, they are completely distinct from those grown in the incubator.

These different modes of evolution can be used for diagnosis by exposing cultures, first, for from twelve to sixteen hours to the temperature of the incubator, and afterward for other twelve to sixteen hours to the temperature of the air.

This done, the colonies show themselves to be constructed with a flat central nucleus, transparent and azure, having a peripheral circle prominent and opaque. This peculiarity, which may be considered

specific, may be made evident in less than twenty-four hours, serving thus to establish the bacteriological diagnosis of the "bacillus icteroides."

Apart from this morphological characteristic, which suffices of itself to differentiate the microbe of yellow fever from all others previously known, the "bacillus icteroides" is endowed with some interesting biological qualities.

It is a facultative anaerobe, and does not resist the Gram stain; it ferments insensibly lactose, more actively glucose and saccharose, but is unable to coagulate milk; it does not produce indol, and is very resistant to drying; it dies in water at 60° C. or after being exposed for seven hours to the solar rays, and lives for a long time in sea water.

The microbe of yellow fever is pathogenic for the greater number of the domestic animals. Few microbes have a pathological dominion so extended and so varied. Birds are completely refractory, but all the mammiferous animals upon which I have experimented have shown themselves more or less susceptible.

But of all the animals, that which lends itself best to showing the close analogy, anatomically and nosologically, between experimental yellow fever and human yellow fever, is the dog.

The virus should be injected into a vein. The morbid process that results manifests itself almost immediately, with a violence of symptoms and an assemblage of lesions which recall the picture, clinical and anatomical, of human yellow fever.

The lesions found after death are extremely interesting, as they are almost identical with those observed in the human cadaver.

Attention is called before everything to the intense fatty degeneration of the liver. The hepatic cell, examined in a fresh state with a little osmic acid, appears completely turned into fat, as it is in human victims of yellow fever; the yellow-fever toxin, as we shall see later, is a true specific poison to the hepatic cell, as are phosphorus and arsenic. A complete fatty degeneration of the liver may be effected by injecting directly into it, through the abdominal parietes, a fresh culture of the specific bacillus.

The kidney shows a severe fatty degeneration, accompanied by lesions of acute parenchymatous nephritis, which may be considered the direct causes of the anuria and the uræmic intoxication.

The digestive apparatus shows lesions of hemorrhagic gastro-enteritis as intense as those caused by poisoning with cyanide of potassium. They are completely analogous to those in man, though more grave.

A bacteriological fact of great interest in the yellow fever of the dog is that in the majority of cases the "bacillus icteroides" is found in the blood and the organs in variable quantity and in a state of absolute purity; at times, it is found associated, as in man, with the coli bacillus and the streptococcus.

As the tendency to secondary microbic infections has been proved even in the yellow-fever intoxication of the dog, provoked with a pure culture, filtered, it must be concluded that the yellow-fever poison, whether by itself or whether through the alterations it produces in the different viscera, and especially in the liver—which, as is well known, should be considered the organ of defence against microbes—favors in the dog secondary infections having their point of departure in the intestinal canal.

This is an important point of resemblance between the yellow fever of the dog and that of man.

From the results of the first part of the investigations relative solely to the comparative morphology, biology, and pathology of the "bacillus icteroides," we can deduce some fundamental conclusions concerning the etiology and the pathology of the yellow fever of man.

Yellow fever is, then, an infectious disease, due to an organism well defined and susceptible of being cultivated in the common artificial nutritive media.

This micro-organism, which I have designated provisionally with the name of "bacillus icteroides," can be isolated, not only from the cadaver, but also during the life of the yellow-fever patient.

Its isolation presents generally difficulties, sometimes invincible, due in part to the constant presence of secondary infections, and in part to the relative scarcity of the organism in the body.

These secondary infections, due almost always to certain species of microbes, as the coli bacillus, the streptococcus, the staphylococcus, the proteus, etc., may appear in the organism long before the death of the patient, which is often attributable to their action rather than to that of the "bacillus icteroides."

It is probable that the protean character of yellow fever in man may be due to the nature and the mode of evolution of these secondary infections.

Yellow fever progresses in cycles; at first the specific microbe is very scarce in the organs, and it is only at the end of the disease cycle, whose duration may be established as between seven and eight days, that the microbe multiplies resolutely and suddenly invades the entire organism, accompanied almost always by other microbes, probably of intestinal origin.

The "bacillus icteroides," once in the organism, not only determines a general intoxication, but also produces specific alterations, which have their seat of election, above all, in the kidneys, the digestive tube, and the liver.

As the renal lesion is one of the first, and as the anuria it provokes establishes itself promptly, to it may be attributed an influence not to be despised in the evolution and termination of the disease.

The patient with yellow fever is in reality menaced by three imminent dangers at the same time, and the bacteriological examination may show, with sufficient exactness, the principal cause of death:

1. It may be attributed chiefly to the specific infection, when the bacillus is found in the cadaver in sufficient quantity and in a state of relative purity; this is seen solely in those cases that complete their morbific cycle.

2. It may be considered as produced by the secondary septicæmia, supervening in the course of the disease, when the cadaver offers cultures, almost pure, of other microbes.

3. It may be attributed in great part to the renal insufficiency, when the cadaver is almost sterile and when the quantity of urea in the blood is very high and death comes on before the disease has terminated its normal cycle of evolution.

It is difficult to pronounce during life upon the respective importance of the uræmic and of the specific symptoms. The frequency of the complication of renal insufficiency is, without doubt, the chief cause which prevents the adoption of a specific thermic type for yellow fever.

The "black vomit" is due to the action of the gastric acid upon the extravasated blood in the stomach. The vomiting itself is directly provoked by the specific emetic action of the toxins of the "bacillus icteroides" circulating in the blood.

The "bacillus icteroides" possesses morphological characteristics so marked that it can be distinguished with much ease from all the other microbes known until now.

Once isolated, whether from the cadaver or from the patient, its exact bacteriological diagnosis does not require more than twenty-four hours.

The disease may be transmitted experimentally

even by the respiratory tract to rabbits and guinea-pigs; the bacteriological examination of these cases shows, at least, the existence of a toxic process identical with that which takes place in man. It is then possible that the contagion of the virus of yellow fever may be effected even by means of the air, which is in accord with the dominant opinions in this respect.

The virus of yellow fever possesses three chief pathogenic properties, which join to give it a peculiar physiognomy that may be considered specific:

1. The steatogenous property, which acts with greater intensity the higher in the zoölogical scale the animal experimented upon is. The jaundice, which appears in general when the illness is advanced, is due in large measure to the anatomical alterations of the liver, which constitute a mechanical obstacle to the free course of the bile, and thus favor its reabsorption by the lymphatics.

2. The congestive and hemorrhage-producing properties which, in spite of being common to other varieties of virus, constitute a salient, specific characteristic, since to them are due not only the classic black vomit and the various other hemorrhages from the mucous membranes, but also the vascular congestions that are the chief cause of the pathognomonic pains of yellow fever—headache, backache, liverache.

3. The emetic properties which, even if they are not so closely connected with the yellow-fever virus as are the preceding manifestations, impress, however, upon this virus, by the rapidity, intensity, and frequency with which they manifest themselves in man and the superior animals, a very particular pathogenic character that distinguishes it easily from all others hitherto known.

On account of the numerical scarcity ordinarily of the "bacillus icteroides" in the human organism, and the violence of the symptoms that occur immediately after the intravenous injection of a culture relatively small, we must suppose the existence of a specific poison, extremely active. We will occupy ourselves, then, with this poison, which is obtained, like that of diphtheria, by simply filtering cultures in broth of the "bacillus icteroides," twenty to twenty-five days old. The yellow-fever poison tolerates almost with impunity heating to a temperature of 70° C., but the heat of ebullition weakens it sensibly.

If the sterilized culture with ether is employed instead of the filtered culture, the toxic power is sensibly augmented.

In the dog the toxin reproduced the same symptoms and the same lesions we have described in speaking of our experiments made with the virus. The bacteriological examination showed the existence of mixed infections, due, as always, to the coli bacillus, or the streptococcus, or the staphylococcus.

The cat is the most resistant animal I have yet made experiments upon.

In the goat the toxin produced exactly, with the exception of the vomiting, the same lesions that have already been noted in the dog and in man.

The horse is very sensitive to even minute quantities of the toxin. An autopsy upon the body of a horse which died from the effects of the toxin showed great swelling of the spleen, a slight degeneration of the liver, nephritis, albuminuria, and some foci of enteritis.

These are the experiments the most important and the most convincing, for the reason that they fix in a definite manner the specific character of the microbe I have discovered, and contribute more than anything else toward a revelation of the secret mechanism of its action upon man.

Up to the present time almost every sort of means has been tried in order to transmit yellow fever experimentally. These attempts gave no results, which explains why for many years the conviction has prevailed in the United States that this terrible malady was not contagious.

A perfect explanation of the surprising failure of these experiments is to be found in the fact that the black vomit was commonly believed to contain the virus of yellow fever, and this was consequently used in trying to communicate the disease.

Now we have seen that the "bacillus icteroides" not only does not have its seat in the stomach, but also, even when it is found by chance in that organ, it is because it has been drawn along by the blood, and is found consequently in a condition of extreme dissolution.

My experiments upon man reach the number of five.

For reasons easily understood I have not used living cultures, but simply cultures in broth from fifteen to twenty days old, filtered with the Chamberland filter and sterilized, moreover, with the greatest caution by a few drops of formic aldehyde.

In two of the individuals I tried the effect of subcutaneous injections and in the other three that of intravenous injections. These fortunate experiments, though few in number, are sufficient to illuminate in a manner unhoped for all the pathogenic mechanism, so obscure and so badly interpreted until now, of yellow fever.

The injection of the filtered culture in doses relatively small reproduces in man typical yellow fever. The fever, the congestions, the hemorrhages, the vomit, the fatty degeneration of the liver, the headache, the backache, the nephritis, the anuria, the uræmia, the jaundice, the delirium, the collapse—in fine, all that conjunction of anatomical and symptomatic elements which constitute by their combination the indivisible basis of the diagnosis of yellow fever, I have seen unroll before my eyes, thanks to the potent influence of the yellow-fever poison made in my artificial cultures. This fact not only represents very valuable evidence in favor of the specific nature of the "bacillus icteroides," but it establishes new grounds for the etiological and pathological conception of yellow fever.

Eliminating thus the dominant theory, which presented the digestive canal, and above all the stomach, as the focus of the disease, solely because the gastro-intestinal phenomena have attracted until now most vividly the attention of the student of disease; demonstrating thus that all these imposing phenomena are due to the specific poison, fabricated by the microbe which circulates in the blood, yellow fever enters immediately the same group of diseases in which I have for some time placed another great morbid process, which, previous to my investigations, had always been ill understood. I refer to typhoid fever.

All the symptomatic phenomena, all the functional alterations, all the anatomical lesions of yellow fever are but the result of the action, eminently steatogenic, emetic, and hæmolytic, of the substance manufactured by the "bacillus icteroides."

It is justly on account of its general symptoms, its characteristic ataxo-adynamic manifestations, its tendency to hemorrhages, its jaundice, etc., that yellow fever has been compared to the poisoning caused by the venom of certain serpents.

Another point of contact between the two morbid processes consists in the hæmatogenic gastro-enteritis, which in cases of poisoning by venom is attributed erroneously, even to-day, to a species of "the force of elimination of the organism."

Now that we have eliminated the way of ingress of the specific microbe and the seat of election, entirely arbitrary, assigned to it in the digestive tube according to old-fashioned ideas, let us see by what route

this microbe penetrates into the organism in order to manufacture its poison, and let us say at once that it is a point sufficiently difficult to establish.

In countries where the yellow fever exists, no evidence has yet been collected sufficiently significant to establish the transmission by water. On the other hand a great number of facts exist which should speak strongly in favor of transmission by the air.

The only example always cited by authors, referring to the diminution of the yellow fever in Vera Cruz since the city was provided with good drinking-water, can have only a relative value, as have all the affirmations of this kind.

There is too exclusive a tendency to attribute to the realization of a single hygienic measure the sanitary improvement of a city; it concerns almost always, on the contrary, a series of hygienic improvements that have of a necessity preceded or accompanied it.

For the rest, the tenacious resistance to desiccation and to water I have found in the "bacillus icteroides" authorize me to admit that the diffusion of the virus of yellow fever can take place as well by air as by water. The experiments on animals show that infection by the respiratory tract is possible.

With respect to the mechanism of infection by the way of fluids, a fact beyond doubt is that when the epithelium of the digestive tract is intact, in general it does not permit the entrance of any sort of pathogenic germ. It should be remembered, notwithstanding, that, in countries where the yellow fever exists, the slightest disorder of the digestive functions, the abuse of alcoholic and iced drinks, and of fruits, etc., above all by new-comers, constitute, as all of them causes of general depression, just so many factors to determine at once the entrance of yellow fever upon the scene.

The marked tendency to lesions of the liver in hot countries would represent then not only one of the conditions that predispose most readily to yellow fever, but, when this has once been established, would be the chief cause of those secondary infections which impress at times a physiognomy so complex upon the bacteriological result of yellow fever and which contribute undoubtedly in a notable manner to the increase of the mortality, already horrible, of this disease.

The "bacillus icteroides," whether by the effect of its specific poison or whether through the grave hepatic lesions which are its most immediate consequence, favors at a given moment the entrance into the organism of septic microbes, which not only end the disease much before the specific agent could do it, but are also prejudicial to the latter, invading at once its domains, suppressing its vegetative faculty and even its vitality.

It is on account of this that these phenomena of microbic antagonism between the yellow-fever bacillus and the micro-organisms of septic infections, instead of being useful to the patient, tend to hasten his death.

There is another curious bacteriological phenomenon of immense value in the epidemiology of yellow fever; the marine propagation of this disease is now completely established, the cause of which we must seek, guided by the knowledge we have acquired concerning the biology of its specific microbe.

The behavior of yellow fever on ships differs singularly from that of another grave epidemic disease—the cholera. The latter, once introduced on board, causes a veritable explosion, attacking rapidly, one may almost say, all it ought to attack.

The gravity of this explosion varies according to the quantity and the energy of the cholera vibrios and the predisposition of the subjects; but this, as it were, act of presence once accomplished, the cholera vibrio does not seem to find in the ordinary nautical conditions a soil very favorable to its existence. Failing this intermediary between man and the cholera agent, above all if disinfection is well carried out, the disease dies out.

Yellow fever on the contrary, once established on a ship, persists long and tenaciously, keeping itself especially in the bilges, holds, storerooms, and finally in every narrow and confined place. It is generally admitted that old and worn ships are the very worst for service with countries in which yellow fever is epidemic. All students of naval hygiene consider as types of "the yellow-fever ship" those ships badly ventilated, with small hatches and air ports, in which vitiated air stagnates above and fetid moisture below.

Heat, moisture, darkness, and want of ventilation seem to be the best coefficients for the preservation of the "bacillus icteroides;" but we know in the present state of our knowledge it is not possible to attribute any specific value to these diverse coefficients, since on the whole they are conditions that favor all microbes in general. It is necessary then to seek in some other concomitant element the cause that gives to the nautical habitat of the "bacillus icteroides" a form almost specific.

A simple phenomenon which attracted my attention under various circumstances during my studies explained to me in an original manner the probable cause of this mysterious longevity and resistance of the "bacillus icteroides" on board ships; it is that the common moulds of the atmosphere constitute the great protectors of the "bacillus icteroides."

The microbe of yellow fever, though endowed with a notable power of resistance to the natural chemico-physical agents, cannot be indifferent with respect to the substances necessary for its nutrition.

It is indubitable that during its saprophytic existence outside the body, as for example in the hold of a ship, it cannot make use of nutritive principles of much value, and this is so certain that many times it is not capable even of multiplying on a layer of common gelatin. If notwithstanding a mould begins to grow in its vicinity, the products of the growth of this hyphomycete or the changes caused by it in the surrounding media are sufficient to nourish, vivify, and multiply the "bacillus icteroides," which otherwise would have been left to die sooner or later. This favorable property of mould for the "bacillus icteroides" can be demonstrated experimentally by placing the spores of any sort of mould upon a layer of gelatin previously sowed with microbes of yellow fever, which, as often happens, has remained sterile.

Scarcely has the mould begun to grow when there appears around it in the gelatin a crown of little punctiform colonies belonging to the "bacillus icteroides." Commensurately with the growth of the mould these colonies become more numerous, augmenting rapidly their zone of occupation around the central stem of the mould. After a few days the plates of gelatin on which the mould has grown presents an appearance extremely curious; around each piece of mould the colonies of the "bacillus icteroides," which one might have supposed for some time to be dead or at least incapable of growing, form, as it were, constellations, the more numerous the nearer they happen to be to the point occupied by the mould. It would seem then that mould possesses a species of radius of influence, within which only is the evolution of colonies of yellow-fever bacilli possible. This radius of influence is more or less extended according to the variety of the mould and the space it occupies, but it is always perfectly regular, uniformly distributed, and equidistant from the centre, represented, as I have said before, by the stalk of the fungus. Outside of this radius of influence, which is always clearly limited, the evolution of the microbe colonies ceases abruptly and the rest of the gelatin remains sterile unless a new

spore gives rise to a new mycelium, which finds itself promptly surrounded by a new pullulation of icteroides colonies.

It is very probable that this faculty constitutes a specific characteristic common to all moulds in general, since the six species I have accidentally isolated from the atmosphere of the laboratory have all shown themselves capable, though in different degrees, of favoring the revivification and multiplication of the icteroides microbe, which without this condition would not have been able to unfold itself.

It is possible, moreover, that there exists in nature, above all in localities where yellow fever takes hold with great vigor, some mould hitherto unknown and endowed with a favoring power truly specific and even much more notable.

This strange phenomenon of parasitism, which could be defined as the loan of the means of existence, this rare form of microbic saprophytism represents probably the easy acclimatization of yellow fever on ships.

It is in reality very probable that in the holds of badly ventilated ships it is not only the legendary moist heat considered from the point of view of its chemico-physical effects which maintains so long the vitality of the yellow-fever germs accidentally brought there. In the holds of ships, in spite of the moist heat, other pathogenic microbes, as that of cholera and of typhus, etc., do not prosper and remain long active. As far as yellow fever is concerned, the moist heat and insufficient ventilation should be considered then as indispensable conditions for the growth of the moulds, and therefore as indirectly favorable to the vitality of the "bacillus icteroides."

This phenomenon of commensalism, analogous to that Metchnikoff marked out some time ago for the cholera vibrio, is in accord with and explains many other well-observed practical facts which form part of the epidemiological character of yellow fever.

We must consider then the moulds as natural protectors of the specific agent of yellow fever, as it is owing to their intervention that the latter finds the force to live and multiply itself until a point is reached at which, through the unsuitableness of the nutritive medium or the action of an unfavorable temperature, its existence would be rendered impossible.

The intervention of this factor, so insignificant in appearance, constitutes notwithstanding the chief cause of the acclimatization of yellow fever not only on ships but also in certain localities where it seems to find conditions extraordinarily favorable for its sad dominion.

We know in truth that one of the conditions thought indispensable for the evolution of yellow fever, moisture, represents, joined with heat, the best element for the formation of the moulds. Moreover it is thought that the unhealthiness of Rio Janeiro is due chiefly to the want of ventilation and to the excessive humidity of the atmosphere.

It is probable then that the factor of humidity on board ship, as near the coast and in the interior of countries, represents the principal coefficient of this biological phenomenon.

Moreover, the conspicuous resistance of the "bacillus icteroides" to desiccation, which is the chief factor of natural disinfection, and its longevity in sea water, explain sufficiently the easy acclimatization of yellow fever and its tenacious persistence above all in maritime localities afflicted by the presence of its specific agent.

For a year, by work often interrupted, I have had the fortune to bring to this point our knowledge this terrible infirmity, which represents the most grave and urgent sanitary problem throughout America. The ground covered is without doubt wide, but there remains yet much to go over. We have learned to know the specific agent of yellow fever; we have it in our power; we have studied minutely its life, its habits, its wants, its relations to external agents and to other small organisms; we have revealed the complicated mechanism of all the infinite manifestations which this agent determines in the human organism, and we have finally placed this disease, which a few months ago was a horrible mystery, on the same level as that occupied by the other great infectious diseases.

The advantages to public prophylaxis and to clinical indications which will rise out of these results need not be indicated; the principal base of social defence against diseases is the exact knowledge of their specific causes.

Asiatic cholera, typhoid fever, and many other grave diseases do not inspire now the terror of former days, because science, relying upon the study of their specific agents, can guard against their diffusion and acclimatization by adopting wise sanitary measures and effecting various hygienic improvements—thanks to the good results of which certain cities have been, so to speak, almost resuscitated.

But apart from the prophylactic ideal, which from the hygienic point of view holds the greater importance, because it is always better and easier to prevent diseases than to cure and drive them out when they have once manifested themselves, there exists another ideal—the therapeutic ideal.

Well, then, given the nature of the process we have just studied, I do not think it difficult for even this ideal to be realized and I entertain a well-founded faith that it will soon be possible to apply to man a specific preventive and curative treatment of yellow fever.

THE TECHNIQUE OF VAGINAL SECTION, IRRESPECTIVE OF HYSTERECTOMY, FOR DISEASED APPENDAGES AND SMALL PELVIC TUMORS.[1]

By AUGUSTIN H. GOELET, M.D.,

NEW YORK,

PROFESSOR OF GYNÆCOLOGY IN THE NEW YORK SCHOOL OF CLINICAL MEDICINE.

In the face of considerable opposition on the part of some surgeons who have obtained most satisfactory results from abdominal section, for these conditions vaginal section has continued to grow in favor and may be regarded as the accepted method of procedure in certain cases. As one of those who at first opposed this route for the removal of diseased pelvic organs, I feel entitled to speak upon this point in the light of recent experience.

My excuse, if one be needed for this brief paper, is to elucidate the technique of vaginal section and the subsequent management of these cases, and thus add my quota to the effort to brush aside the prejudice which still exists in some quarters against the operation. Anything which will lessen the shock in operation, reduce the mortality, and shorten convalescence is to be regarded as a decided advance in our methods, and this may be said of the vaginal operation. If the surgeon selects his cases carefully and employs this method only when it is appropriate, he will have no dissatisfaction with the results, but will soon learn infinitely to prefer this route in certain conditions. There will still remain a great many cases in which abdominal section can be done to better advantage and to the greater safety of the patient. It must not be thought, then, that the one route will entirely supersede the other, since both have their natural limitations,

[1] Read before the section on obstetrics and diseases of women of the American Medical Association, 1897.

based upon (1) the ease with which the operation may be completed, (2) the complications which may develop as the operation proceeds, (3) the danger which the operation involves, and (4) the immediate as well as the remote results, including the necessity for drainage.

The advantages of this method aside from those already mentioned may be stated as follows, viz.: (1) The patient will more readily consent to a vaginal section; hence hopelessly diseased organs may be removed earlier and the mortality thereby lessened and suffering relieved. (2) The surgeon will not hesitate to advise vaginal section in conditions which do not seem to present sufficient gravity to warrant the risk of abdominal section. (3) As a method of exploration of the pelvis necessary to clear up the diagnosis when the diseased condition is not extensive and when adhesions are not dense or numerous. (4) If subsequent drainage is certain to be required, it is more prefectly secured through a vaginal incision.

The operation is applicable (1) for small pelvic tumors which are or seem to be solid in part or entirely so; (2) in ovarian cysts of considerable size, since the fluid can be evacuated and the sac withdrawn through a small vaginal incision and removed quite as readily, and many times more readily than through an abdominal incision; (3) for pyosalpinx, hydrosalpinx, and hæmatosalpinx; (4) for cystic or otherwise enlarged and diseased ovaries; (5) for the removal of small subperitoneal fibroids by myomectomy; (6) for drainage of pus accumulations situated low down in the pelvis; (7) for hæmatoma and hæmatocele; (8) for pelvic exudations which resist other means for their removal. I have had excellent results from persistent faradization in these last-named conditions; hence I believe that surgical interference is seldom required when suppuration has not occurred.

Technique of Vaginal Section.—The patient is as carefully prepared as for abdominal section, and the abdomen should be shaved and otherwise rendered aseptic, so as to permit an immediate section there should the necessity develop during the course of the operation through the vagina. The vagina is thoroughly irrigated the evening before with a one-per-cent. solution of lysol in hot water and packed with markasol gauze. This is preferred because it is certainly antiseptic and does not irritate the vaginal surface. The morning of the operation the vulva is shaved and washed with green soap and a one-per-cent. solution of lysol, and afterward covered with a pad of markasol gauze. After being anæsthetized the patient is placed upon the operating-table in the exaggerated lithotomy position, with buttocks over the edge of the table. The vulva and the vagina are now scrubbed again with green soap and irrigated with a one-per-cent. solution of lysol. A short broad-bladed hard-rubber speculum is inserted and the perineum retracted, exposing the cervix. The speculum is held in the right hand by the nurse, who sits to the left of the operator. The cervix is seized with the angular tenaculum forceps, drawn down, and the cervical canal is dilated; the cavity of the uterus is curetted and irrigated with a one-per-cent. solution of lysol and packed with markasol gauze to the external os. A traction ligature is now inserted through both lips of the cervix, which is held by the nurse with her left hand, who draws it down and up against the pubis if the section is to be made posterior to the cervix. The cervico-vaginal fold is the guide for the line of incision. With curved, blunt-pointed scissors a semicircular incision is made through the vaginal wall along the fold extending about half-way around the cervix on either side. After the vaginal wall has been penetrated, the dissection is extended farther with the blunt end of the scissors closed or with the thumb nail, the operator hugging the posterior wall of the uterus and peeling the tissues away from it until the peritoneal fold of Douglas' pouch is exposed. This is divided with the scissors and enlarged to the extent of the vaginal incision on either side. Up to this point there may be considerable bleeding from small vessels which have been divided, but the operation need not be delayed by any effort to control this until the peritoneal cavity is opened.

The peritoneum on the posterior face of Douglas' pouch is now drawn down with a tenaculum, and with a continuous catgut suture it is sewed to the posterior edge of the vaginal incision to the limit on either side. This very effectually controls the bleeding. A traction ligature of silk is now inserted on either side near the angle of the incision in the vaginal wall, including the peritoneum, which has just been sewed to it. We are now ready for exploration of the pelvic cavity. One or two fingers are inserted, and when adhesions are encountered they are separated; the diseased structure is brought more easily within reach of the examining fingers by pressure upon the abdomen above with the disengaged hand and by removing the perineal retractor.

If a distended tube is discovered or any cystic tumor, care is necessary to avoid rupture and soiling of the peritoneum. The adhesions are carefully separated, and, when possible, the mass is delivered through the vaginal incision, the pedicle is ligated, and it is removed intact. But should it prove too large for removal in this manner, the adhesions are separated as far as it is possible to reach, and it is brought down to the incision and held firmly there by pressure upon the abdomen above, while it is seized firmly and punctured, so that the contents will be discharged along the groove of the speculum. As the sac collapses it is rapidly drawn through the incision into the vagina. Adhesions which could not be reached before can now be separated. If the tumor is a large ovarian cyst, it may be more advantageous to employ a trocar, but I seldom use it. If the tumor proves to be a pus accumulation in the tube or ovary, greater care must be taken to avoid soiling or infecting the peritoneal cavity, and free irrigation of the vagina with a 1 to 5,000 solution of bichloride, if it is ruptured during removal, will be necessary. As a rule, irrigation should be avoided when possible, and I seldom use anything except normal salt solution.

Prolapse of the intestines through the incision is avoided by elevation of the hips and by inserting a pad of sterilized gauze, with string attached for its removal, through the incision up into the pelvic cavity and pushing them out of the way. This is done of course before the mass is brought down into the incision.

A solid or semisolid tumor will be more difficult to remove through a vaginal incision, though I have removed dermoids the size of the fist. Solid tumors attached to the uterus and when not very large may be removed piecemeal, though I prefer abdominal section in these cases.

Small subperitoneal fibroids, when their removal is thought best, may be removed likewise by a myomectomy through a vaginal incision, the pedicle being enucleated from the uterine wall and the wound closed by a Lembert suture of fine catgut.

When the location of the mass is such that it may be reached more easily by an incision anterior to the uterus, the peritoneal cavity is entered by a similar incision in the vaginal wall anterior to the cervix and extending up between the uterus and bladder. It will be safer, especially when there is any prolapse of the anterior vaginal wall, to precede the operation by a thorough exploration of the bladder by means of a sound, so as to locate its position relative to the uterus.

Great care must be observed in the dissection between the uterus and bladder not to wound the latter, and it must be remembered that the dissection must be carried much farther up in front than behind before the peritoneum is reached. By hugging the front wall of the utterus closely, and making traction upon the cervix downward and backward, there will be no excuse for wounding the bladder. When the peritoneum is reached and the cavity opened, the edge of the peritoneum is attached to the edge of the vaginal incision by suture, and we are ready for exploration of the pelvis and the removal of the offending structures. This method of procedure is the same as when the incision is made into the posterior cul-de-sac.

The after-dressing of these wounds in the vagina and their subsequent management will depend greatly upon the necessity for drainage and the liability to adhesions of the intestines to the returned stump. When the character of the work done is of such a nature that drainage is not required, and there is no likelihood that adhesions will form, the vaginal wound may be closed by suture, though this is not absolutely necessary, as union will take place quickly if it is left unsutured. It is not even necessary to remove the catgut suture which unites the peritoneum to the vaginal wall, since the two surfaces of peritoneum will fall together and adhere, and the absorption of the catgut permits the other tissues to come into coaptation subsequently. (The traction ligatures are, of course, removed.) Yet if the catgut has been hardened and we are not certain that it will be quickly absorbed, it should be removed.

When it is thought best to close the vaginal wound a continuous suture of ordinary catgut is employed, and care is taken to include the peritoneal edges in the sutures. Subsequently the vagina is packed loosely with markasol or plain sterilized gauze, which is removed after forty-eight hours. After this the vagina is irrigated daily if required.

When drainage is necessary or adhesions are to be avoided, a strip of plain sterilized gauze is carried through the incision and packed around the returned stump to protect it from contact with the intestines. The end of this is allowed to protrude into the vagina, which is filled loosely with the same gauze. For convenience of removal, the strip carried up through the incision should be continuous with that in the vagina.

This gauze is permitted to remain for twenty-four hours, when that in the vagina should be removed, together with a part of that in the peritoneal cavity. Some fresh gauze is placed in the vagina, and after another twenty-four hours the whole is removed by very gentle traction, and the vaginal wound is permitted to close if there is no longer any necessity for drainage.

Union will usually take place in from six to eight days, even when the gauze drain is employed, and the patient can be gotten up at the end of two weeks if nothing occurs to prevent it.

It is the exception when any rise of temperature follows this form of vaginal section, and the convalescence is, as a rule, rapid and uneventful.

128 West Seventy-Third Street.

Uterine Sound.—The use of the uterine sound to reduce retrodisplacement of the uterus, although recommended by some text-books, is never to be resorted to. The dangers from liability to perforate the organ, of carrying infection into its cavity, or of injuring its mucous-membrane lining so that germs that are already present may invade the tissues, are too great to warrant the risk. The sound should never be used for this purpose.—Montgomery.

Progress of Medical Science.

Poisoning by Quinine.—Gresswell (*Lancet*, May 1, 1897) has reported the case of a woman, forty-seven years old, to whom he was called because it was thought she had fallen into a fit. He found her prostrated, unable to speak, and with a pallor of countenance like that of impending death. On inquiry it was learned that the patient had taken before breakfast, about two teaspoonfuls of quinine dissolved in acid after which she vomited. The hands and face were extremely pale and the pulse was quick and irregular—almost fluttering, small, thready, and feebie. The heart beats, though clear, were wanting in strength, and were of a dull, subdued, metallic character. Hearing was entirely lost and vision was greatly impaired. For about eight hours the woman remained speechless and quiescent, though not quite unconscious. At the end of this time she began to speak, while some color had returned to the cheeks and the action of the heart had become quieter and stronger. A sedative prescription insured a comfortable night and on the following day the patient was much improved, although still deaf, especially in the right ear. The pupils were large and reacted but sluggishly. Perfect recovery ensued in the course of a few more days. In describing the onset of her symptoms the patient stated that she at first felt faint, then dizzy, and was next sick; tingling appeared in the fingers and all over the body; and finally unconsciousness developed without pain.

The Variability in Color and Amount of the Intracellular Biliary Pigment Deposits in the Liver.—As the result of a study of pathologic changes in liver cells, Browicz (*Deutsche medicinische Wochenschrift*, June 3, 1897) comes to the conclusion that the beginnings of the biliary capillaries are to be found within the protoplasm of the liver cells themselves, appearing as intraprotoplasmatic biliary passages in direct communication with the intracellular biliary passages. The so-called secretion vacuoles of Kupfer may be looked upon as transverse sections of intraprotoplasmatic biliary passages. In cases of pronounced intracellular stasis of bile, the intraprotoplasmatic passages may furnish the basis of pathologic vacuolization of the liver cells of varying degree. The nucleus of the liver cell takes an active part in the secretion of the biliary pigment. The deposition of such pigment within the nuclei of liver cells under pathologic conditions is not indiscriminate in distribution about the reticulum, but takes place within well-defined rounded areas, so that the conclusion seems justified that permanent spaces or canals are present in the resting nucleus, which become distended under pathological conditions and afford the basis for pathologic vacuolization of the nucleus. Continued investigation upon the same lines has shown that within the chromatin ground substance of the nucleus of the liver cell there exists a system of fine spaces or canals in direct communication with the intraprotoplasmatic system of canals, and this in turn is in direct communication with the intracellular biliary passages. The intranuclear and intraprotoplasmatic system of canals must be considered a connected system of secretory canals, as indicated by the various biliary deposits that take place in them under pathologic conditions. The beginnings of the biliary passages would thus have to be located in the nucleus of the liver cell itself. Pathologic vacuolization of nuclei, as well as of the protoplasm found in association with pathologic states of the liver cells, is intimately connected with the existence of an intranuclear and intraprotoplasmatic secretory canal system.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, July 24, 1897.

THE PATHOLOGY OF RECURRENT APPENDICITIS.

WHETHER every case of appendicitis should be treated surgically or not, even when the most approved medical measures have failed to effect speedy relief, and whether or not the diseased appendix should be removed invariably, are still debatable questions. There can be no doubt that in many instances recovery, from the immediate attack at least, ensues without surgical intervention, and it is even probable that some attacks pursue a favorable course without so much as being recognized, though less commonly at present than in the not remote past. Death from peritonitis of obscure origin also is less common now than formerly.

When, however, one reflects upon the frequency with which an attack of appendicitis is followed by others when the diseased organ is permitted to remain, it becomes an exceedingly delicate matter to decide in the individual case whether it is better to undertake a radical operation or to submit to the uncertain risks and dangers that attend a lesion of undeterminable extent and degree. While the mortality from the disease may not be greater in competent medical than in equally competent surgical hands, the future of the case appears assuredly less certain under the former than under the latter conditions. The final decision, however, in favor of the one or the other course of procedure will depend ultimately upon a thorough appreciation of the pathology and the natural history of the morbid process.

It is for this reason that a recent report by Southam,[1] of the pathological conditions found in twenty cases of recurrent appendicitis treated by operation, will be received with especial interest. Of this number seven occurred in females and thirteen in males. The youngest patient was ten, the oldest forty-four years of age. In fifteen of the cases the patients were between fifteen and thirty years of age. In all of the specimens examined the appendix showed evidences of chronic inflammatory changes, with thickening of its coats. In some cases its lumen was uniformly narrowed and almost obliterated; in others it was partially or completely occluded at some point and dilated on the distal side of the obstruction, occasionally forming, when the occlusion was complete, a cystic cavity of some dimensions. In many instances the appendix was considerably shortened; it was frequently found bent upon itself and bound down by adhesions, in one case the tip almost touching the cæcal end of the process.

The contents of the appendix consisted either of clear mucus or of a muco-purulent fluid; in two cases a hard fæcal concretion was present in its interior, and in another a concretion which had ulcerated through its wall was found in an abscess cavity external to it. In most cases the inflammatory changes were not confined to the appendix itself, for evidences of appendicular peritonitis were generally found to be present, the peritonitis being usually of the adhesive variety, the inflammatory exudation that had been poured out round the appendix having undergone organization and forming adhesions. These were often very firm and extensive, surrounding the appendix and fixing it to the parietal peritoneum, omentum, cæcum, or small intestine. In some instances they were present after a second attack; in other instances they were absent after many attacks. When exceptionally dense and extensive, complete obstruction of the bowel may be produced from inclusion and compression of a small coil of small intestine in the adhesions, and if the condition is incapable of relief by operation the result is necessarily fatal.

In some instances the peritonitis was of the suppurative character, pus having formed in the neighborhood of the appendix. This complication was encountered in eight of the twenty cases. In six of these the suppuration was localized, an encysted intraperitoneal abscess being present. In two cases the suppuration was general, there being well-marked evidences of diffuse purulent peritonitis. When suppuration takes place it is often secondary to ulceration and perforation of the walls of the appendix, followed by escape of its contents. In one case the appendix, though not actually perforated, was extremely thinned at one point, which was found to correspond with an ulcer involving its mucous and muscular coats.

Among the twenty cases the duration of the symptoms ranged from four months to six years, and the number of attacks from two to ten or more. If cases of recurrent appendicitis are left to themselves attacks may recur at irregular intervals for years, and ultimately a cure may take place by a gradual process of obliteration of the lumen of the appendix and its conversion into a fibrous cord. Suppuration may, however, occur at any time; if an encysted abscess forms, the appendix should, after evacuation of its contents, usually shrivel up, becoming obliterated and causing no further trouble. On the other hand, if the suppuration is diffuse—that is, if there is general purulent peritonitis—the result will probably be fatal. Another complication, already mentioned, that may occur is intestinal obstruction from compression of a coil of bowel by adhesions.

Of the various theories advanced to explain the occurrence of appendicitis, the most plausible is that which regards the appendix as a diverticulum that readily allows of the accumulation and stagnation of

[1] The Lancet, June 5, 1897.

fæcal matter. This, mingling with the secretion from its mucous lining and undergoing fermentative or putrefactive changes, sets up a catarrhal inflammation, which may be followed by ulceration and perforation, or by thickening of its walls, the latter condition being that which is most commonly encountered in the recurrent form of the disease. The fæcal concretions found in the interior are probably the consequence and not the cause of the inflammation, being due to inspissation of its contents; but once formed, they no doubt tend to excite and keep up the recurrent attacks.

ENGLISH AND ITALIAN EXCLUSIVENESS.

English medical practitioners in Italy are bitterly complaining of an attempt that is being made by the medical profession in that country to prohibit by law physicians with foreign diplomas from practising there without having first obtained an Italian qualification. Americans, too, are interested in the matter, and they probably have more right to complain of this proposed treatment than the English. The Italians in this respect are but following in the footsteps of most of the other nations of Europe, and perhaps can hardly be blamed for endeavoring to protect the interests of their own medical men. The English deny that a man with a foreign degree is not allowed to practise in England, and it is certainly true that he can practise there, but he is so hampered by restrictions that the leave to do so is of no use. Unless a foreigner is registered he cannot recover fees by legal process, or give medical evidence in courts of law, or hold public offices, and, lastly, he may not sign a death certificate; so that in reality these restrictions act as a bar to his practising at all.

From a perusal of the British medical act of 1886, there would seem to be no especial difficulty in regard to the registration of a good foreign degree. The paragraph referring to foreign registration provides that a person who desires to be registered as a foreign practitioner must prove to the registrar that he holds a recognized foreign diploma granted in such a foreign country, and also that he is not a British subject, or that the diploma was not granted while he was domiciled in the United Kingdom, or was granted in the course of a period of not less than five years during which he was resident out of the country, or that he was practising in the United Kingdom on the said date and had been practising there or elsewhere for not less than ten years immediately preceding. He will then, on the payment of a fee not exceeding $25, be entitled to be registered without further examination. A recognized foreign diploma is one which is recognized for the time being by the General Medical Council as furnishing a sufficient guarantee of the possession of the required knowledge and skill for efficient practice. Although the Privy Council has power to override the decision of the General Medical Council, as a matter of fact, the recognition of equivalent qualifications rests with the Medical Council. Major Greenwood, M.D., in an article published in the *Medical Magazine* of 1894, says that the medical profession in England is quite in accord that it is highly desirable that the right to practise medicine there should not be granted to those who possess only a foreign degree. Foreign degrees are practically shut out by refusing to allow them to be registered, and this action is due to the opposition of the corporate degree-granting bodies. In Great Britain foreign degrees can be registered only when the applicant holds an English qualification. There is not on the British medical register the name of one man who holds only a foreign degree. There are few medical schools granting degrees or qualifications, even in the colonies of Great Britain, which are recognized as granting a right to practise in the United Kingdom. Thus it would seem that to all intents and purposes Italians desirous of practising medicine in England are prohibited to as great an extent as Englishmen will be in Italy if the new proposals become law. The United States, so far as the regulations ruling the practice of medicine are concerned, holds a different position in regard to Italy than England does, and is deserving of better treatment at her hands. Even in the States in which a four-years' course is compulsory, any foreigner possessing an equivalent diploma is allowed to present himself for examination, and if found competent is granted a license to practise.

However, after all, the question will most probably resolve itself into one of money. When the pecuniary situation is grasped by the Italian mind, and it is perceived that to drive away English and American doctors would be to drive away also English and American residents and tourists, the matter will present itself in a different light. When the interests of the country at large are seen to be seriously threatened, as they certainly would be by this change, more prudent counsels will prevail and affairs will be allowed to remain in *statu quo*. *The Lancet*, in a short article on the subject, speaks to the point: "Italy depends too much on British, American, and Anglo-colonial gold to thwart the requirement of its distributors. About one-third of her annual revenue is derived from the Anglo-American sources alone. To enact a law, therefore, which would tend to diminish her English-speaking population (resident or migratory) would be little short of suicidal. If it ever found a place on the statute book, the government would forthwith be besieged by the combined hotel-keeping and 'pension' interest clamoring for its immediate repeal."

VACCINATION IN AFGHANISTAN.

A notable triumph has been won in the field of scientific progress, and this, too, by a woman. The Ameer of Afghanistan, ruler of one of the most savage of races, has, through the influence of his private physician, Miss Hamilton, M.D., become a convert to a belief in the inoculation theory. Miss Hamilton visited England last summer with the Ameer's son, when she obtained a model for a stable for calves which are used for the purpose of procuring calf lymph. When she returned to Cabul she initiated the Ameer into the mystery of vaccination. The Ameer, who has on many

occasions showed his appreciation of the improvements of civilization and more particularly when they have seemed likely to benefit his country, was much impressed by what he learned of vaccination as a safeguard against small-pox. As Afghanistan is visited every year in the springtime by an outbreak of small-pox in virulent form, it has been decided to establish vaccine stations and to endeavor to inculcate in the minds of the warlike but uneducated Afghans the immense protection afforded by vaccination. Miss Hamilton is the only European physician in the country, so that the task of introducing vaccination and of educating the inhabitants to receive it will be a heavy one. If Miss Hamilton succeeds in her endeavor, it will be a notable triumph for her individually, and will also reflect credit on the ever-increasing body of women doctors. It is to be hoped that the antivaccinationists of England, who are very rabid at the present time, when they hear of the project in Afghanistan, will not forthwith dispatch some of their loquacious disciples to Afghanistan and inaugurate in that country a crusade against this life-preserving measure.

News of the Week.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending July 17, 1897. July 12th.—Surgeon C. G. Herndon ordered to special duty at naval rendezvous, Duluth, Minn., July 19th. July 16th.—Assistant Surgeon S. B. Palmer detached from the *Texas*, and ordered to the *Annapolis*, July 20th; Assistant Surgeon F. L. Pleadwell detached from the *Constellation*, July 17th, and ordered to the *Texas*, July 20th; Passed Assistant Surgeon G. B. Wilson ordered to the *Constellation*.

Dr. Frederick Holme Wiggin has been appointed a delegate from the New York State Medical Association to the Montreal meeting of the British Medical Association.

Obituary Notes.—Dr. James A. McLochlin, of this city, died at his summer home in Saratoga on July 16th, of renal trouble. He was forty-eight years old and was a graduate of the New York University in 1874. He was a member of both the County Society and the County Association.—Dr. Robert S. Hubbard, of Bridgeport, Conn., died at his home in that city on July 18th. His death was the result of a fall on his office steps. He was unconscious when picked up, and died in a few hours without recovering his senses. He was a graduate of the Yale Medical School in 1851.

The Missouri Medical League of St. Louis is the name of a newly organized society of medical practitioners in St. Louis, modelled after the New York Medical League. It is stated in the *Medical Review* that the organization is the outcome of the recent investigation of the committee on clinics and dispensaries appointed by the St. Louis Medical Society, and has for its object the elevation of the medical profession by influencing legislation to require a higher standard of general education before students can matriculate at a medical college and a higher standard of requirements for graduation in medicine. The suppression of free-dispensary and clinic abuses, *et id genus omne*, the fostering of fraternity between the members of the medical profession, and the support of a movement to secure a national department of public health, are also among the aims of the society. The first meeting of the new organization was held on July 1st.

The Society of Neurologists and Psychologists in Moscow has appointed a special committee to report upon the present state of inebriety in that city, and to draw up a plan for the erection of a hospital for inebriates.

The Health of Chicago.—For the week ended June 27th, the *Evening Post* states, the mortality rate in Chicago was 10.99, said to be the lowest ever reported for any large city.

Inspecting Water Tanks.—The inspectors of the New York City health department have been examining the water tanks on the roofs of the tenement houses, and have found many of them in a filthy condition. Wherever they were found to be dirty, the owners of the buildings have been forced to have them cleaned.

Safety at "Dead Man's Curve."—The killing or maiming of innocent pedestrians by the cable cars at Fourteenth Street in this city has now been abolished by the threat of the board of health to hold the officers of the company responsible if cars were run on the curves at a greater speed than two miles an hour. As soon as it became a question of personal safety to themselves, the officers of the company suddenly discovered a grip by means of which the speed of the cars could be easily regulated. Truly, "necessity is the mother of invention."

Small-pox in Mexico.—A dispatch from Pueblo says that black small-pox is epidemic there, and that many deaths have occurred.

A Possible Plague Ship.—A ship recently arrived at San Francisco from India has been quarantined, awaiting a determination of the nature of an illness from which one of the crew had died and two others were convalescent, the health officers fearing from the description given that it may have been the bubonic plague.

Collapse of a Nursing-Scheme in Canada.—The governor-general of Canada and Lady Aberdeen proposed recently to organize a "Victorian Order of Nurses," whose object would be to supply trained nurses to care for the poor. The governor-general, with infinite tact, issued a pamphlet in favor of the scheme, in which he remarked incidentally that "Canada needed more Dr. MacLures—men who were not in the profession for the sake of the fees alone." Much to the author's surprise and pain, this did not serve to

recommend the project to the men in the profession who were dependent for their living upon their fees, and they have expressed themselves so forcibly against such a method of commemorating the jubilee that its collapse is well-nigh assured.

A Case of Misplaced Confidence.—A man was recently arrested here for having perpetrated a fraud upon two eclectic practitioners in this State. According to *The Sun*, the doctors state that the man had some preparation which he said would remove superfluous hair without injury to the skin. They believed in his representations without first trying the preparation on hair, and got a paper from him which gave them the exclusive right to sell the preparation in their county. In consideration of the privilege, they gave him $125 and bought a lot of the preparation. They had large quantities of advertising matter sent out, extolling the drug, and soon began to treat patients. The preparation did not remove hair, and they say that their reputations have been injured and that they are out of pocket.

The British Medical Association.—Over two hundred members of the association in England have signified their intention to take part in the Montreal meeting.

The Right to Practise Dentistry in Scotland.—In the case of a man who had been prosecuted for the illegal practice of dentistry, the appeal court of Scotland has decided that for a person to put up a brass plate with the inscriptions "American Dentistry, A. Emslie" and "Dental Office," is not an offence against the dentists act, as it does not necessarily imply that A. Emslie is qualified and registered. The person, whose dentistry may really be as bad as the worst Scotch instead of being American, as his sign would imply, has the right therefore to continue his practice without let or hindrance.

Entertainments for the Members of the Moscow Congress.—A number of entertainments in honor of those who take part in the international congress will be provided for after the sessions have closed. One of these is an excursion to the health resorts in the Caucasus, during which many of the cities in southern Russia will be visited. The entire cost of the trip of ten days' or two weeks' duration will be only about $30. For those who prefer to go to St. Petersburg, there will be several receptions arranged for by the local entertainment committee under the chairmanship of Professor Pashutin, president of the Russian Medical Council and director of the Army Medical Academy in St. Petersburg. The following entertainments have been arranged: On August 28th a reception by the members of the profession and medical societies in the Salle de Noblesse. On the 29th there will be an excursion to Peterhof, with supper in the park, at the summer house of Monplaisir, and, on the same evening, a "rout" given by the Princess of Oldenburg. On the 30th the new anatomical museum in memory of Pirogof is to be formally opened in the morning, and in the evening there will be a "rout" given by the municipal authorities. August 31st and September 1st are to be given up to an inspection of some of the medical and other institutions of the city. A ladies' committee has been formed in connection with the congress, under the presidency of Mme. Skliffosofski, the wife of the president of the organizing committee. Members who expect to be accompanied by ladies are particularly requested to communicate the fact to the general secretary, Professor Roth.

The List of the Scottish Jubilee Honors is as long as the famous chapter on snakes in Ireland, and those who hoped to be knighted don't know what to make of it. The *British Medical Journal* tries to console the Scots by telling them that the Queen loves them and esteems them, and that she will doubtless give them at some other time the plums which it has pleased her in her wisdom to withhold from them on this glorious occasion.

Koch's Report on the Plague.—The Berlin correspondent of *The Sun* states that Koch has made a report giving the result of his investigations into the bubonic plague in India. He says that the bacillus possesses but little vitality outside of the bodies of men and animals, and adds that Haffkine's serum possesses undoubted protective qualities.

A Leper Dead in Jersey City.—A man supposed to be affected with leprosy, whose case has excited much interest here and across the river, died last week at his home in Jersey City. He was a motorman on a trolley road, and first noticed the skin trouble, which was originally thought to be eczema, about two years ago.

Casualties at the Jubilee Celebration. — Many prophets of evil foretold a great loss of life and much painful maiming in the crush of people assembled in London to view the jubilee procession, but their prognostications proved false. In spite of the fact that temporary stands were erected at all available points along the entire route, and of the more important fact that they were all filled to their utmost seating-capacity, not one collapsed. No one of those standing along the line was crushed to death, and most of the cases attended to by the medical corps, only two hundred and one in all, were of simple fainting. The number of accident cases treated in the hospitals was below the average of ordinary days, owing doubtless to the fact that wagon traffic was suspended in great part.

Injury to the German Emperor.—While cruising on his yacht one Sunday recently, Emperor William of Germany was struck on the head with some swinging cordage. The cable reports that one of his eyes was seriously injured, and that Duke Charles Theodore of Bavaria, an ophthalmologist, has been summoned to Kiel to examine him.

Professor von Kölliker, of Würzburg, the famous histologist, celebrated, on July 6th, the completion of his eightieth year and the golden jubilee of his professorship.

Sir James Reid, physician-in-ordinary to Queen Victoria, has been created a baronet by his grateful patient.

Society Reports.

AMERICAN MEDICAL ASSOCIATION.

Continued from page 121.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN.

THE first day's session was called to order by the chairman, DR. MILO B. WARD, of Topeka, Kan., who delivered the

Annual Address.—The "healthy mother" is one of the most important subjects which can to-day engage the attention of physicians. To the work of Sims and Emmet, as pioneers in American gynæcology, was paid a due tribute, and the history of operations upon the female pelvic organs in America was passed in review from the earliest days. To American surgeons is due to a large degree the position now held by these branches of medicine. Gynæcology as a specialty can be said to date only from about 1869. The first society was formed in that year in Boston. To-day every well-equipped medical college has a full professorship of gynæcology. Conservatism should always exist, but its limitations should be more clearly defined. Electricity for the cure of fibroids and pelvic exudates is attended by so much harm at the hands of tinkers and unqualified operators that it has perhaps unjustly fallen into disrepute. The last word on the question has not yet been spoken, but only those fully qualified should attempt its use. A higher standard of qualification in those who attempt operative treatment in general of pelvic disease is called for. Many complications still baffle the most expert operators. The use of clamps instead of suture in vaginal hysterectomy was deprecated. It is always well to have the best clamps at hand, but it is best not to use them. Ligating the arteries for the cure of uterine fibroids has not yet been proven a successful procedure. A tribute was paid to the work of Philadelphia obstetricians and gynæcologists.

Uterine Retroposition.—The first paper, entitled "A Consideration of Some of the Conditions Influencing the Results of the Surgical Treatment of Uterine Retroposition," was read by DR. AUGUSTUS P. CLARKE, of Cambridge, Mass. The fact that various methods of treatment for versions and flexions have been devised is suggestive that the application of the means of relief for the presence of such pathological conditions has been attended with more or less difficulty. The various ligaments sometimes become inflamed, thickened, and pulpy. In such cases the connective tissue which penetrates their structure becomes vascular; this condition leads undoubtedly to the transformation of the parts. In other instances the round ligaments undergo fatty degeneration and atrophy, and become incapable thereby of sustaining the organ in its natural position. The occurrence of these changes is for the most part secondary to inflammation of the adjacent structures. In such cases the fundus will in all probability be found firmly adherent posteriorly.

After the lacerated tissues of the cervix and perineum have been repaired, an operation for shortening the round ligaments may be undertaken, should the displacement backward still continue to give rise to marked uncomfortable symptoms. If, however, the adhesions cannot be overcome and there are thickening of the fundus and induration of the corporeal structures of the uterus, due to metritis and peritoneal inflammation, the operation upon the ligaments would be contraindicated. Sudden and severe strain put upon the ligaments, such as may take place in lifting heavy bodies, is always to be avoided after the patient has found it necessary to submit to treatment for uterine displacement. Restoration of the perineum can almost always be safely undertaken, but, in order to have good results by combining with it the operation of narrowing the posterior wall of the vagina, it will be essential that the uterine corpus shall be brought into as nearly a normal condition as is possible.

Recent experiences have to a considerable extent dissipated the unfounded fears that the anteverted state of the uterus produced by the shortening of the round ligaments would interfere with subsequent pregnancy and parturient processes. The Alexander operation when resorted to in properly selected cases is not a mutilation; by it is removed no organ nor any structures that are ever regarded as essential to the normal function and to the perfection of the organism. The operation removes only tissue that has become excessive by cytogenic processes. The danger that hernia will follow the operation of shortening the round ligaments has been felt to be an objection to the procedure. Though such a sequel sometimes ensues, yet, if proper precaution be taken to effect ablation or narrowing of the inguinal canal, the risk will be reduced to the minimum. When hernia does appear after the operation, it is, according to the author's observation, mostly in those cases in which the inguinal canal is abnormally large and in which the muscular element in the vicinity has previously undergone atrophy and relaxation.

Ventrosuspension, hysterorrhaphy, vaginal fixation, cystopexy of the uterus, and operations upon the utero-recto-sacral supports are liable to be unfavorable as to their subsequent influence on pregnancy and parturition.

In those cases of retroposition in which it has become necessary to remove the adnexa on account of inflammation or other morbid conditions, the pedicles can be sutured to the peritoneum and to the peritoneal fascia on each side of the incision. Two small sutures may then be passed through the fundus to the anterior wall of the abdomen. This method of proceeding will firmly sustain the uterus, and will in most instances prove sufficient without the necessity of resorting to Alexander's operation. The sutures thus taken in such cases are rather compensatory than otherwise for the loss of uterine supports resulting from the removal of the adnexa. There is a rare class of cases in which but little if any perimetric adhesive inflammation occurs. In cases of this latter variety, as in all others of retroposition, there is a complication of more or less prolapse of the organ. Indeed, it is hardly to be conceived how a retrodisplacement can result without the previous occurrence of some degree of descent of the uterus.

In those cases in which the patient has reached the menopause and in which the backward displacement has been attended with complete and irreducible prolapse, hysterectomy will prove the most advisable for insuring permanent relief.

DR. HALL, of Missouri, thought too many hernias result from the Alexander operation. The future operation for retrodisplacement is fixing the uterus forward through the vagina, as described by Vineberg. This fixes it in a more nearly normal position without the disadvantages of the Alexander operation.

DR. HUMISTON, of Ohio, failed to find an indication for the Alexander operation. A radical operation is called for if there are diseased adnexa.

DR. MASSEY, of Philadelphia, did not believe that inflammation preceded the displacement, as a rule, but followed it.

DR. KANE suggested causing patients to assume the knee-chest position, with calisthenic exercises. This is the next best thing to having the patient walk on all fours.

DR. NEWMANN, of Chicago, did not think the round

ligaments have any supportive power, but shortening them will do something if sufficient support from below is furnished.

Dr. Lawrence, of Columbus, said the symptoms from which these patients suffer are not dependent upon the displacement but upon the diseased adnexa, endometritis, etc.; and here the Alexander operation is not devoid of danger. Peritonitis may follow. Ventral fixation cannot be expected to benefit the patient if it is true that anteversions and anteflexions are about as bad as the posterior. The broad ligament is the true supporter, and by shortening it we might accomplish our purpose.

Dr. Clarke, in closing the discussion, said if the parts below have been restored, unless the round ligaments are diseased, they will be adequate to hold up the uterus.

Mechanism and Treatment of Perineal Lacerations was the title of a paper by Dr. Joseph Price, of Philadelphia. Many men say they have never ruptured a perineum. Such a statement can have but one explanation. More attention should be directed to perineal lacerations, and the functions of the tissues involved should be better studied. Attempts at repair should be undertaken only after a full apprenticeship has been served in delicate mechanics. Nature despises blundering as she does a vacuum. Completeness should be the chief aim in plastic surgery of the perineum, and the attempt made to restore the parts to as near the normal as possible. Every perineal tear begins on the inside. Outside tears without internal laceration are of extreme rarity. One should remember always that the skin may not be lacerated in very extensive tears. Complete tears include all muscle and fascial tissues, and should be repaired in the line of their anatomical construction. Flap-splitting operations are misleading and fallacious, superficial procedures, not going to the real origin. An end-to-end adaptation of the torn muscle must be substituted for them. The Emmet operation is the foundation for all operations in deep tears, either with or without involvement of the sphincter. The sphincter is a distinct anatomical unit. When the sphincter ani is ruptured, the muscle is straightened, the depressions on either side of the anus being caused by the retraction of the torn ends. Short strong needles and good silver wire, a needle-holder without lock, a shot compressor and tenaculum are all that is required. The restoration of the pelvic floor is the ideal operation for the exaggerated tears, as shown in Baker-Brown's book.

Dr. Stone, of Washington, thought the Emmet operation was as difficult to comprehend as anything in surgery. To make certain points clear he drew diagrams of the crown suture, as applied by himself. He thought Emmet was seldom followed in his plan of introducing all the sutures before tying any. The crown suture is applied from the myrtiform caruncles upward and inward, emerging at a corresponding point on the opposite side. In tying, the vagina is shortened.

Dr. Price said the end of the muscle is the last part to be denuded. To do this a tenaculum must be buried into the muscle and repeated stitches passed deeply. All secondary operations on the perineum should be obviated by immediate operation without anæsthetics at the time the tear occurs. There is no danger and no difficulty in this. All operations following the line of Emmet's operation must of necessity be in the nature of modifications.

Dr. MacDonald, of Albany, said that some have to continue doing a flap-splitting operation, and this, too, with satisfaction to the patient. Here you must first undo the scar effect, following the lines of scar and separating the anterior from the posterior tissues. Buried fine catgut or Lembert suture enables one to restore the rectal functions with resiliency of tissue.

Dr. Eastman said the anal sphincter must be completely dilated and put at rest one week before operation. No process of sterilization is capable of cleansing the operator's hands, so an assistant must do all dilating at the time of operation.

Dr. S. M. Hay, of Toronto, Canada, being introduced to the section, said he regretted there had been any differences of opinion between Canada and the United States in regard to the British Medical Association meeting. Political difficulties might now and then arise, but the professional relations should always remain pleasant.

Dr. Goldspohn, of Chicago, said that perineorrhaphy proper must be done from within the vagina; hence the Lawson Tait procedure should naturally be condemned. It is not necessary to sacrifice tissue. He carried out flap splitting, but beginning within the hymen.

Dr. Fisher, of Philadelphia, had seen many flap-splitting operations, and they do not stand the test of time. Central laceration not involving the sphincter does not occasion prolapse. In lateral lacerations and those involving the sphincter, the Emmet operation is required. The posterior wall is here held up against the anterior. The crest of the rectocele is that point which corresponds with the opening of the urethra anteriorly. All do not follow this rule, which, however, is the first to claim attention.

Dr. Humiston operates without general anæsthesia, using less than one grain of cocaine by injection, or forty minims of a two-per-cent. solution.

Dr. Price, in closing, said silver acts as a splint to the tissues, but silkworm suture does the same to a lesser degree. Shouldered and shielded silver wire gives the most valuable suture. It comes out dry.

The Technique of Vaginal Section, Irrespective of Hysterectomy, for Diseased Appendages and Small Pelvic Tumors was the title of the next paper, read by Dr. A. Goelet, of New York (see p. 122).

In the discussion Dr. Howard Kelly, of Baltimore, preferred vaginal section in instances presenting relaxed vagina, and especially Edebohls' method to secure free drainage. Extra-uterine pregnancy, when pelvic hæmatocele is present, is best treated by this method. In extreme bleeding he advises proceeding with abdominal section.

Dr. Eastman, of Indianapolis, said he would not consent to operate in the exaggerated lithotomy posture, preferring the Sims position for all vaginal operations.

Dr. Goelet said some conservative work can be well done through the vagina, and infection from the cervix is more imaginary than real.

Renal Suppuration and the Value of Micro-Urinalysis as an Aid to Its Definite Diagnosis was discussed in a paper presented by Dr. F. H. Manly, of New York.

In the discussion Dr. Duning said pyonephrosis affecting one kidney alone is a curable disease. He considered that the discovery of pus coming from one or the other side before it reached the bladder was of importance. He spoke of a case of multiple abscess of the kidney with small calculi in the abscess cavities. In one instance he opened and drained, with amelioration of all symptoms. Abscesses developed in other points, and the kidney was removed. The value of bladder exploration with the cystoscope and head mirror was spoken of. The ureter can be catheterized, and in this way the side affected can be made out.

Dr. Noble, of Atlanta, spoke of the absolute diagnosis being made possible by the catheter introduced into the ureter with the aid of cystoscopic examination. This is of more importance than examination of the urine for pus.

Dr. Manly, in closing, said the catheter had a very limited application in male subjects, especially those with stricture.

The Destiny of Vaginal Hysterectomy for Malignant Disease was discussed in a paper by Dr. L. C. Hall, of Kansas City, Mo. The discovery of cancerous disease is often made only after the cervix has been destroyed. The author made a strong plea for early and frequent examination, so that these cancers of the uterus may be early discovered and operated upon. Most cases when presented are inoperable, at least by the vaginal route. We are forced to admit that the latter for the majority of cases is a doubtful expedient. The danger of invasion of other important structures precludes the possibility of complete removal. The method which permits of inspection must become that of election. The author thought that Clark's method will supersede vaginal hysterectomy.

Dr. Janvrin, of New York, said these patients usually came to the surgeon so late that vaginal hysterectomy was seldom justified. He had thus operated many times for cancer. Women ought to come at an earlier stage, in which the cervix alone may be affected. In the majority of cases operation in the early stage, while the patient is still free from general systemic infection, offers the best chances of cure, and in all such an operation can be successfully carried out. He had reported statistics last year, showing that thirty-three per cent. of his cases were still living. When the glands are involved in a late stage, the disease is sure to return.

Dr. Eastman advocated operation in desperate cases to relieve the patient from the disagreeable features of the progressing disease and to prolong life. It is justifiable to operate even late for the relief afforded. In cancer of the fundus perhaps better results are to be expected than when the cervix is involved. We must go wide of the disease. The pedicle can be well fixed within the wound, so that any return of the disease can be noted.

Dr. Dudley, of New York, said the destiny of vaginal hysterectomy for malignant disease depends simply upon diagnosis. If the uterus is free, vaginal hysterectomy is a proper operation. If any portion of the vaginal wall or broad ligament is involved, another operation is called for—a combined method. No one can tell how far the disease has gone when the broad ligaments are involved.

Dr. Frederick, of Buffalo, reported a case bearing on the rapidity with which cancer progresses. The patient was still alive and in fair condition after seven years, without operation.

Dr. Kelly thought that these cancers should be taken out by the way of the abdomen, even removing glands lying on the abdominal aorta.

Dr. Janvrin asked for statistics.

Dr. Kelly said the immediate mortality was greater, but the ultimate results must be better. Every woman over thirty years of age should be examined three months after bearing a child, and the condition noted. In this way many cancers can be discovered early enough to give good chance of success.

Dr. Price said, in reply to Dr. Dudley and others, that in going up to a certain point in operation was good theoretically, but difficult to carry out. He preferred the vaginal route to all others, excepting in the complications on the part of the tubes and ovaries referred to by Dr. Dudley. Here he preferred to attack from above. Recurrences in the bowels and abdominal organs often cause horrible death.

Dr. Thompson spoke of the importance of early and exact diagnosis, not only in cancer of the uterus, but of the breast.

The Treatment of Circumscribed Pelvic Hemorrhage was the title of a paper next read by Dr. M. Rosenwasser, of Cleveland, Ohio. The causes are numerous; many instances are due to extra-uterine pregnancy. Unless there is absolute indication for immediate operation, rest under restriction, in hospital if possible, is advised. Instances from a large number of personal cases were related. When watched, over half will recover if put upon perfect rest for six weeks. The conclusions reached by the reader were:

1. That unless they require immediate operation for cause when first seen, they can be submitted to careful supervision in hospital or home without danger.

2. That when thus watched, more than one-half will get well without operation, by keeping them at absolute rest for an average period of six or eight weeks.

3. That when they cannot be watched, or refuse to rest, early operation is to be urgently recommended.

4. That operation is necessary only for special indications, of which the most important are sepsis with or without suppuration, recurrent hemorrhage, growth of tumor, non-absorption after reasonable time, the compression of the pelvic viscera (rectum or ureters).

5. Abdominal section is to be preferred to vaginal incision in most cases.

Dr. McMurtry, of Louisville, said that as our knowledge has increased, the matter has become simplified. Many terms for intrapelvic hemorrhage should be dropped. Almost all instances are due to ruptured tubal pregnancy.

Dr. Goelet could not believe that pregnancy was nearly so often the cause as claimed. The thing to do is to remove the clot.

Dr. Noble had not seen hemorrhage due to other cause than tubal pregnancy. He operates as soon as the diagnosis is made, and has lost no case when tube and clot were removed.

Dr. Dunn said if the rupture occurs early it may not be necessary to remove the tube.

Dr. Dudley thought there were other causes than extra-uterine pregnancy. One of the many causes is the puncture of a midwife in producing abortion. Patients come into the hospital septic after such attempts. Ulceration attended with hemorrhage at the extremity of a tube may account for a clot.

Dr. Duff, of Pittsburg, thought that in most cases of sudden hemorrhage it was due to extra-uterine pregnancy. He thought the danger of puncturing the uterus was greater than is usually admitted. He reported an instance of fatal puncture.

Dr. Cordier thought this paper might set us back ten years. He agreed as to the cause of hemorrhage, but he was unable to understand how the diagnosis is made that the hemorrhage is circumscribed or will remain so. Most cases develop rupture before the twelfth week. Operation should be done by the abdominal route at the time of sudden hemorrhage.

Dr. Kelly said that when circumscribed and held down the patient with hemorrhage could be safely left under rest and observation.

Dr Rosenwasser said this was the third report he had made on the subject. He had no hobby to ride, but reported cases as they occurred. If the truth can "set back" anything, he wished it set back.

Some Reflex Disturbances Due to Pelvic Disease, with Report of Cases, were discussed by Dr. J. M. Duff, of Pittsburg. The following cases were reported:

Case I.—Metritis and ovaritis, insanity. Vaginal hysterectomy, cure of insanity.

Case II.—Removal of tubes and ovaries for inflammation, followed by mania (suicidal) and mental disease, lasting one year. Final recovery.

Case III.—Constant vomiting, reflex from cystic ovary. Removal of ovary; prompt cure.

Case IV.—Constant vomiting; patient nourished for eighteen weeks by enemata. Removal of pus tubes,

followed by cessation of vomiting and cure of patient.

Case V.—Sciatica of two years' standing, patient unable to walk. Cured promptly by removal of diseased tube and ovary on the same side.

Case VI.—Epileptoid seizures continuing for eight years. Insomnia and general neurotic condition, probably cured by removal of the uterus and appendages. Time since operation too short to draw positive conclusions.

Dr. Kelly said the paper well illustrated the fact that in treatment the pelvic organs cannot be separated from the whole system.

Dr. Tuttle said we must establish an increased nutrition of the nerve centres in these cases by rest, over-feeding at regular intervals, and regulation of the functions, with increased secretion.

Dr. Goldspohn spoke of relieving severe sciatica by removing the appendages.

Dr. Duff related an instance of epileptoid seizure before and after operation, in which the post-mortem revealed cerebral tumors, explaining the failure of the pelvic operation to give relief.

The Midwife Question in America was discussed in a paper by Dr. C. S. Bacon, of Chicago, Ill.

Dr. Duff thought clandestine midwives should be compelled to leave the field. To accomplish this, legitimate midwives should be licensed, and they would soon drive out the wrongdoers.

Dr. Baldwin, of Columbus, thought there was a place in this country for the educated midwife. The physician could not afford to give the time to the proper treatment of prolonged obstetric cases. In the Columbus school an attempt had been made to establish a midwifery school, but it had not succeeded. We must look to legislation backed by public sentiment.

Dr. Burns thought that in large cities the dispensary would solve the problem and make the midwife soon a thing of the past.

Dr. Newmann thought Chicago was indebted to Dr. Bacon for the work he has done in this line. Many districts are not reached by the dispensary, the lady physician, or the trained nurse, and we must come to depend upon the midwife, who should be under careful supervision. Dr. Bacon thought it unwise to make paupers of the class who now employ midwives. There are too many paupers already. Four-fifths of obstetric cases are now attended by midwives.

New Advances in the Treatment of Fibroid Uteri, a paper by Dr. Howard A. Kelly, of Baltimore, was next read. He predicted that the next great wave of advance would be in the line of conservatism. He advocated conservative treatment of myomatous uteri. He would excise any number of myomata and sew up the incisions. This in large uteri is more difficult than to remove the whole uterus. If the patient's condition is good, and an operation lasts but fifty minutes, and the patient is under thirty-seven years of age, myomectomy should be done. A free incision is made, the uterus is lifted out, and the tumors are then excised. A uterus thus treated is somewhat analogous to a Cæsarean uterus with multiple wounds. The speaker said he had made as many as nine incisions. The cavity is usually not opened, but he has opened it from end to end. In one case the entire anterior wall of the uterus was removed, leaving only the mucous surface of the posterior wall. This operation conserves a natural function which is a distinctive attribute of sex.

Vaginal Section in Extra-Uterine Pregnancy.—Dr. Lewis Schooler, of Des Moines, Iowa, read the paper. By this is meant an ample enough opening for the extraction of fœtal membranes. To-day, contrary to what was taught in former times, the diagnosis of extra-uterine pregnancy can be made with accuracy. The writer did not believe that hernias are so frequent in the vaginal as in the abdominal method. If after a lapse of time the vaginal operation is found to relieve a large percentage of cases, it will have a place; otherwise it will become a forgotten method.

Dr. Rosenwasser said that, while free to operate, he did not think, as Drs. J. and M. Price did, that every case of extra-uterine pregnancy should be operated upon. Many patients get well.

Dr. Duff said his experience justified him in saying that every case should be operated upon. He had seen patients perish who refused operation. We cannot always determine which are the safe cases to leave. We should always be ready to do transfusion with the normal salt solution by the direct method.

Dr. Schooler said few cases could be operated upon successfully through the vagina.

Dr. M. Price said we must not only operate, but operate at once without a moment's delay, by the upper route in preference.

Extra-Uterine Pregnancy, with Report of Cases, was a paper by Dr. M. Price, of Philadelphia. A series of cases was related, showing the results of operation. The urgent indication is the immediate stoppage of hemorrhage; the only way to do this is to open the abdomen and tie the vessels, no matter in what condition the woman may be, so long as she is not dead.

The Vaginal Route in Operation for Ruptured Tubal Pregnancy was the title of a paper by Dr. J. Wesley Bovée, of Washington, D. C., in which he stated that many cases of rupured tubal pregnancy probably escape attention, owing to the slight discomfort of the patient or to improper diagnosis being made and procrastination permitting nature to cure the condition. This class, however, he thought is a very small minority, else more of such cases would be found as a complication when abdominal section is made. He claimed that many cases that are treated are slight and not very dangerous in themselves. These cases can in many instances be treated by operation through the vagina, and to substantiate his claims he referred to the work of Kelly, Miller, and others and reported six successful cases of his own treated in this manner. His conclusions were: 1, that the vaginal route is preferable for operation for ruptured tubal pregnancy when the hemorrhage has ceased or is slow, when the escaped blood is limited to the pelvic excavation, and especially if a limiting diaphragm has formed above it; 2, that the vaginal route is freer of shock, is less liable to permit infection, and furnishes better drainage; 3, that there is less liability to removal of adnexa than when the abdomen is opened; 4, that the period of convalescence is shorter and devoid of the usual complications of abdominal section.

Injuries of Parturition; the Time, Methods, and Reason for Repair.—Dr. A. H. Tuttle, of Cambridge, Mass., was the author. The paper was introduced with the report of a case of severe laceration repaired one week after the accident. The writer pointed out the fact that many obstetricians neglect to make a careful examination of their patient at the close of labor, and that unless this is done in good light, turning the vagina out and inspecting the cervix and deepest portions of the vagina, it is impossible for them to form any idea whatever of the extent of the injuries. He went on to describe the various lesions, and pointed out with emphasis that the subperitoneal space is frequently opened by a tear through the cervix that passes beyond its junction with the vagina, and also by a direct tear of the vagina in its deepest portions, at the sides and vault, entirely distinct from the tears extending from the perineal body up the lateral sulci, and which in extreme cases extends the full length of the vagina along the sides, parallel to the urethra and terminating in the tissues that form the prepuce of the clitoris.

He claimed that if both of these tears are not satisfactorily repaired at the time of injury, healing will occur by secondary intention, a mild or severe infection follows, and the patient after a protracted convalescence is left with a uterus fixed high and the ovaries bound down by adhesions. The path of infection is direct and not by the way of or necessarily involving the uterus. He recommended the primary repair of all lesions of parturition, this to be done in the same careful manner as is ordinarily exercised in a secondary operation, with the patient on a table, plenty of assistance, and strict antiseptic and aseptic measures. If the accident occurs at night and assistance is not at hand, the patient should be given ergot, the blood squeezed out of the uterus, and an aseptic pad applied. The case can then be left for from ten to twenty-four hours to suit the convenience of the attendants. He claimed that repair can be done as easily at the end of ten hours as at the end of the first, if the raw surfaces are slightly scraped with a knife or sharp curette, and that the cervix, owing to the retraction of the uterus, can be treated much more easily. He employs animal sutures in the repair of the parts. The lacerations of the rectum, skin, and mucous membranes are closed with buried sutures, a fine strand being used for each, and the torn edges of the muscles are brought back into exact apposition and in the same position they occupied before the accident by figure-of-eight suturing and a number of superficial layers. In closing the rectal and vaginal tears the necessity of starting the suture high enough to close tightly the upper angles was carefully pointed out.

The results of the operations were almost uniformly perfect. In one case the stiches gave way, but the wound was opened up, cleaned, and repaired again, a few days after the first operation, and healed by primary union. In three cases stitch abscess formed, opened outward or into the vagina, and healed spontaneously, leaving a very satisfactory perineum. In his conclusions Dr. Tuttle said that in the lives of many women there is no time more opportune for the repair of the parts than that occupied for her convalescence from labor, and that a perfect operation will shorten this period; that the public should be instructed in the fact that injuries during parturition are unavoidable and cast a reflection on the obstetrician only when their careful repair is neglected; that the best way to avoid a suit for malpractice for these injuries is to call in assistants who act as witnesses, and to repair or offer to repair the parts; that old tears may be repaired at the same time; that the obstetrician should be better educated in the repair of these injuries; that a satisfactory repair of the injuries at the time of their occurrence is the best way to prevent a majority of the ills of women which arise from disease of the pelvic organs.

Dr. Duff said lacerations are much more frequent than is usually believed. The profession is blamed for laceration because of the popular and occasional professional ignorance of this frequency; some look upon the intact external skin as an evidence that there is no laceration. No one thing so indicates the difference between the general and special practitioner as this failure to discover a tear in the presence of intact skin. We must be honest with one another and acknowledge these failures.

Dr. Hall said he believed in making repair as soon as one can get the instruments sterilized and dressings ready. There should not be too much trimming of tissues.

Dr. Allen preferred to wait until the second or fourth day. He thought there was no more danger of sepsis and indeed less.

Dr. Fisher believed laceration of the pelvic floor extremely frequent. That of the perineum is usually insignificant; without involvement of muscle, it is an external wound easily repaired. He prefers the interruptured suture, and operates without anæsthesia. As an antiseptic eucaine is employed.

Dr. Da Costa said that tears in the perineum proper occur in thirty per cent. of cases; many do not need attention. Physicians fortunate enough to have had no tears to report may be incapable of recognizing them. As soon as the placenta is delivered, he would cleanse and approximate at once with suture without trimming the parts; the latter fall into place in the healing. Failure is rare. Serrefines will answer for moderate cases.

Fibroid Tumor of the Vagina, with the Report of a Case, was the paper by Dr. J. M. Emmert, of Atlantic, Iowa. The paper was based upon an investigation of the subject by a circular letter sent out to a large number of operators, and upon the author's personal experience. Twelve published and twelve unpublished cases were reported. Out of sixteen patients, ten were over thirty and under forty years of age. The attachment was reported as being: in ten in in the anterior, in five in the posterior, in two in the lateral walls. The history and subsequent histologic examination proved the author's case to have been one of fibroid. The tumor was enucleated by incising about the base and peeling out the tumor. In the investigation five or six cases were excluded from the literature as doubtful.

One Hundred Cases of Atresia and Stenosis Vaginalis in Labor, with Thirteen Fatal Cases, was the title of a paper by Dr. J. J. E. Maher, of New York. The oldest case in literature is that observed by Louis, one hundred years ago. The conclusions drawn from all cases and especially the fatal ones are:

1. That from seventy to eighty per cent of all these obstructions being found in the middle third or at the orifice of the vagina, a predisposing condition may be discovered in an increase of the muscular tonus at these points.

2. That the size of the opening does not necessarily jeopardize the result, inasmuch as none of the complete atresia cases proved fatal, and among the fatal cases four had openings large enough for the finger to pass.

3. That the resistance can be overcome in every case is evidenced by the fact that only two of the ten cases termed cartilaginous proved fatal.

4. That the thickness, which in fifteen cases was stated as varying from twenty millimetres to that of the entire length of the vagina, is not an insuperable barrier, for only two of such dimensions were fatal. Of the other two mentioned with a fatal issue, one gave a measurement of twelve millimetres and the other was characterized as thin.

5. That there is practically no difference in the character of the stricture, the site, location of opening, central or not, resistance or thickness, between the congenital or post-partum cases, which amounted to eighty-seven per cent. of the whole.

6. That the complication should not necessarily have been fatal except possibly in two cases, one of contracted pelvis with shoulder presentation, and one of twin pregnancy.

7. That the various methods of treatment applied both to the obstruction and to the delivery do not make a bad showing when it is remembered that many of these subjects were in labor for days before interference was attempted or allowed.

8. A grave error is a misconceived idea of the powers of nature. The author has met with three cases of atresia and stenosis. There was in all an inflammatory condition of the vaginal mucosa behind the barrier.

Studies in Gynæcology from the Service of the Woman's Hospital of Philadelphia.—Dr. Anna M.

Fullerton, of Philadelphia, read the paper. She said that whenever she was able to reach a woman's understanding and secure her co-operation little difficulty was experienced in carrying out suitable measures. Education in physiological laws was called for. As conservers of woman's health physicians should influence the education of young men. Women should be taught the virtue and the dignity of true wifehood and motherhood as controlled by physiological laws.

Dr. Kelly said that doctors are too apt to pass over slight symptoms in their female patients, and neglect leucorrhœas and complaints which if properly managed would not result in more serious troubles. In obstetrics more cleanly attention should be paid the patient. The obstetric binder had better be thrown aside. Personal cleanliness is emphasized by the physician wearing a white duck suit in the lying-in room. The scrubbing brush for the nails should be quite stiff. Less license should be given men in morality.

The Chairman asked Dr. Fullerton her opinion of the effect of the bicycle.

Dr. Fullerton answered that in the absence of pelvic disease it tends to increase the muscular development and does good. After exercise has developed the muscles, walking can be indulged in better than before. There are no bladder troubles arising from the use of the wheel, if the saddle is all right. The corset should not be worn by women in riding.

The Technique of Abdominal Hysterectomy was the subject of a paper read by Dr. J. F. Baldwin, of Columbus, Ohio. His method may be described in brief as follows:

Seizure of the broad ligament with a long clamp from just beyond the ovary to the body of the uterus, above the uterine artery; clamping the ovarian artery near the uterus; severing the broad ligament along the clamp first applied; making a peritoneal flap anteriorly and posteriorly between the tips of the two lateral clamps; separating the folds of the broad ligament between the point of the clamp and the uterus, and seizing the uterine artery; removing the body of the uterus at or below the internal os, making anterior and posterior flaps. The uterine artery is isolated from surrounding tissue and tied as far back as possible with fine silk or kangaroo tendon; the round ligament caught with forceps and the long clamp removed from the broad ligament; the ovarian artery brought out between the folds of the broad ligament and ligated with fine silk or catgut; a gauze drain passed through the cervix from above into the vagina, so as mechanically to clean and dilate the cervix; with kangaroo tendon the uterine flaps are next brought together, the round ligament on each side being brought down and sutured between the flaps; the peritoneal layers of the broad ligament are next infolded and united by a running suture of kangaroo tendon, which passes down to the cervix, uniting the infolded peritoneal flaps over the suture already inserted in the cervical tissue, and then up on the opposite side. As thus completed the pelvic floor is entirely smooth, with no projecting points of raw surface.

The points of novelty claimed for this technique are in the bringing in of the round ligaments and the snug drawing in of the broad ligaments so as to support the cervical plug, which thus sustains the vault of the vagina. The advantages of this method of operating are: (1) Such a shutting off of the vagina as to reduce to a minimum danger of infection from that source. (2) The ligature placed around the uterine artery is entirely outside of the uterine wound, and being buried in the tissues is much less likely to give any trouble. (3) The snug closing of the cervical tissue prevents oozing. (4) The smooth peritoneum in the floor of the pelvis, having no projecting stumps or raw surfaces, reduces to an absolute minimum the danger of intestinal adhesions. (5) The implantation of the round ligaments and the puckering in of the broad ligaments prevent prolapse of the cervical stump and vagina. (6) The use of the clamps on the broad ligaments obviates hemorrhage, leaves the parts in better shape for the subsequent steps of the operation, and saves considerable time.

The paper was based on a study of ninety-five operations, with a mortality of 5.26 per cent.

(*To be Continued.*)

MEDICAL AND CHIRURGICAL FACULTY OF THE STATE OF MARYLAND.

Ninety-Ninth Annual Session, Held at the Hall of the Faculty, April 27, 28, 29, and 30, 1897.

Tuesday, April 27th—First Day.

President's Addresss.—Dr. William Osler delivered the president's address on "Functions of the State Faculty." He spoke of the old age of this society and the fact that only one other organization had a similar name. The need of medical societies is very evident with physicians, as a rule living so much to themselves, and they tend to rub off corners and widen personal interest. As this is the day of consolidation, the speaker suggested that it would be well if all the local societies would consolidate with the State Faculty as sections, just as has been done in the New York Academy of Medicine. The library of the faculty is growing each year and is of great value to the members. The man who does not read books and journals does not keep up with the times. Soon the Faculty will celebrate its one hundredth anniversary, and on this occasion opportunity should be taken to endow the faculty and make it a powerful body in the State.

The Care of the Dependent Insane in Maryland.—This discussion was opened by Dr. E. N. Brush, who was followed by Dr. Henry H. Hurd, of the Johns Hopkins Hospital. The speakers emphasized the fact that the insane were the children of the State and should be taken care of by the State. The insane should not be cared for in almshouses, where the number of attendants is small and the conditions are not favorable for recovery, but in a special hospital for their treatment. The lunacy commission of Maryland does the very best it can, probably, with the laws which are on the statute book, but the laws are very defective and vague, and throughout the smaller towns and counties of the State the physicians for the insane, being appointed politically, take very little interest in their work. The papers of commitment are often faulty; the statistics of insanity in Maryland also are not reliable, and it is not likely that any one knows how many insane persons there are. Many could recover under proper treatment, and they require more than good food and clothing.

In answer to these statements, Dr. William Lee, the secretary of the lunacy commission, said that since the organization of this commission in 1886 there had been a gradual improvement in the care of the dependent insane and that this had gone on from year to year; that while there might be some objections as compared with States much wealthier than Maryland, and the insane might be made more comfortable under other conditions, still the commission has done its very best under the existing laws.

Dr. Rohé also spoke on the same general subject, and said that in his opinion the insane were better cared for than they were formerly.

Peritonitis.—This was a special subject for discussion at this session. Dr. Simon Flexner spoke of the pathology and etiology. This is a very large subject and the manner of approaching it is difficult. The peritoneum is able to resist a great deal and it can dispose of foreign substances up to a certain limit. Not all parts of it carry on absorption, but only a limited portion, that near the central tendon of the diaphragm. Stomata between the endothelial cells do not exist, but fluids may pass through, and even solids sometimes escape; they are carried through by cells. Some substances interfere with this power of absorption, but quite an amount can be absorbed, and even bacterial organisms can be destroyed as long as the peritoneum is intact. At the Johns Hopkins Hospital he had records of one hundred and ten cases of acute peritonitis in man, with the bacteriological examination, and these cases were divided into certain groups. We must admit, first of all, an idiopathic or primary peritonitis. Twelve idiopathic cases were in this number. In all these cases there were pre-existing conditions predisposing to this peritonitis, such as chronic heart disease, chronic kidney disease, etc. Persons subject to chronic diseases are more liable to bacterial infection. In several cases the peritoneum was one of several serous surfaces involved in the body. There were thirty-three cases of exogenous peritonitis, in which the invasion was from without, and in those cases laparotomy had been performed and certain other operations had been done. Finally there is an endogenous form, in which the infection is from within; it is an intestinal form. Fifty out of one hundred and ten cases which he found recorded were in the intestinal tract, from a perforated appendix or some such cause. In studying the bacteriology of these cases it is interesting to note that in the first group the staphylococcus aureus and the streptococcus are present as mono-infections. In the second group there are some mono-infections and many poly-infections, such as by the staphylococcus, the streptococcus, and the colon bacillus, etc. In the third group infection usually comes from some injury to the intestines; there is a poly-infection, such as by the streptococcus and the colon bacillus together. Septic peritonitis and suppurative peritonitis are terms used as if they designated distinct conditions. Peritonitis in the absence of the micro-organism is very rare indeed, but it may occur. The fibrino-purulent form is the one more usually met with. The mycotic form is one in which the symptoms run such a rapid course that there is little time for the formation of bacteria and there is very little reaction on the part of the peritoneum. This division, however, is not necessary.

Dr. S. C. Chew said that the diagnosis of peritonitis was sometimes easy and sometimes very difficult, and again there were varying shades of difference between these two extremes; in general it is easy when the case is typical. The person's history in the case is important. He instanced conditions that may be mistaken for peritonitis.

Dr. Charles M. Ellis, of Elkton, said it is not easy to draw a sharp line of demarcation between medical and surgical peritonitis; the surgeon is not so successful. If the operation is done after the tenth day the chances are good, but many cases recover anyhow: still after ten days recoveries are more frequent than is commonly supposed. Many cases belong to surgery from the beginning. Nature seems to understand the treatment by fixing the parts. Besides this, treatment should be supplemented by rest, little food by the mouth, saline cathartics at the beginning, and opiates.

Wednesday, April 28th—Second Day.

Rabies.—Dr. John Ruhräh spoke of the preventive treatment of rabies. The disease is very common where there are no dog laws, but where there are a high dog tax and careful supervision there are few cases of hydrophobia. The inoculation period is about ten weeks, although it can be as short as two or three. The shortest on record was twenty-six days, while in one case it was eighteen months. Deaths in three weeks are rare. In the cases which were reported, about forty-seven per cent. of those bitten developed the disease. Men have a greater mortality than women, and children the greatest of all. Eight per cent. of suspected cases developed. When the wound was immediately cauterized the mortality reached only thirty-three per cent. of the forty-seven per cent. mentioned above, while in the uncauterized it reached eighty per cent. In the department of the Seine mortality of hydrophobia was twenty-five per cent. the first year in the Pasteur Institute, and sixteen per cent. the second year. The virus affects chiefly the central nervous system. In preparing virus for use on man a rabbit is inoculated from a rabid dog. Pasteur's idea was to make a modified form of the disease.

Dr. William H. Welch said that in drawing conclusions it is well to remember such a disease as hydrophobia exists. This is unquestionable. Mistakes occur, but the disease has characteristic symptoms. Inoculation in animals in series is a positive pathological proof of the existence of the disease. The state of mind has nothing to do with the matter, nor the element of fear, any more than syphilophobia can cause syphilis. The method of treatment rests on a complicated experimental basis, which is just as satisfactory as is the treatment of diphtheria. The best way of finding its value is by the statistical method and by this we show that the treatment is efficacious. It is not a sure cure; failures occur, but are not numerous.

Microscopical Examination of Milk.—Dr. William Royal Stokes, bacteriologist to the health board of Baltimore, briefly reviewed the methods used in the municipal laboratory in examining milk. When the milk examined was from one cow, or even when it was a mixed milk from many cows, it was centrifugalized for some minutes and then the sediment was spread out on a glass and stained. If many pus cells were found the specimen was rejected; but if there were only one or two pus cells in the field the specimen was passed.

Food Adulterations.—Dr. J. C. Hemmeter read a paper on the above subject, in which he spoke first of beer adulteration, and said that the beer made in Baltimore was especially free from adulterants, while the imported beer was not so good, on account of the salicylic acid put in to preserve it during export. The water of Baltimore was especially good and contained very few organisms. He had examined a great many oysters and had failed to find any typhoid or pathogenic bacteria. He thought that the tidal waves of the Chesapeake Bay and lack of contaminated water kept the oysters free from disease.

Thursday, April 29th—Third Day.

The Early History of Ophthalmology and Otology.—This was an interesting historical sketch by Dr. Harry Friedenwald, who said that as early as 1805 reference was made to licenses for oculists in Baltimore. Dr. Pierre Chatard, who came from France in his early life to Baltimore in 1797, was a prolific writer, and contributed articles on diseases of the eye. Other writers, as Dr. William Gibson, Dr. George Frick, Dr. Cohen, Dr. Jameson, and Dr. Harper, show

that the diseases of the eye and ear received very early attention in Maryland. In fact, Dr. Frick's book was the first to appear in English on the subject in Baltimore and the third in the English language.

Fracture and Dislocation of the Vertebral Column.—Dr. R. Percy Smith, of Sunnybrook, Md., exhibited a case in which a weight of five hundred and fifty pounds had fallen on the back of a man, and had both fractured and dislocated his vertebral column and injured his skull. The patient is able to go about and his recovery is remarkable.

Two Cases of Gastrotomy and One of Gastro-Enterostomy.—Dr. Robert W. Johnson exhibited one of his patients entirely well. She was a young girl who had severe vomiting before the operation of gastrotomy, and after the operation had never vomited; she now considered herself well. In one case he recovered a long bonnet pin. In this case of gastro-enterostomy the patient died.

Dr. Hemmeter referred to the cured patient as one in whom he had used the electric light in the stomach, showing the dilated condition of that organ, which extended below the symphysis.

Plaster Jacket versus the Steel Brace in the Treatment of Pott's Disease.—Dr. R. Tunstall Taylor showed five children who were undergoing treatment for Pott's disease. He thought that the plaster jacket gave good support when the curvature was below the seventh cervical vertebra; above that point the steel back brace was best.

Suppurative Otitis Media with Symptoms of Sepsis and Intracranial Disease; Recovery under Mastoid Operation and Removal of Polypi.—This was a very elaborate paper by Dr. Hiram Woods, Jr., showing the importance of attending to certain running diseases of the ear which appear harmless, but which in reality are dangerous.

Does Medicine Advance? was the subject of the annual address by Dr. David W. Cheever, emeritus professor of surgery, Harvard University. The speaker took up the various departments of medical science and analyzed the changes in the past years, and drew conclusions showing that medical science had advanced all along the line.

After the address a banquet was served.

Friday, March 30th—Fourth Day.

Models of the Original Chamberlen Midwifery Forceps.—Dr. J. Whitridge Williams showed models of forceps used by the Chamberlens at the end of the sixteenth century. He had obtained these models through the courtesy of the Royal Medico-Chirurgical Society of London. One pair showed how little change had been made in the forceps in all these years. Some of the blades were tied together by tapes, and some had mortise locks.

The Common Contagious Diseases of the Skin in School Children.—This was a very practical paper by Dr. T. C. Gilchrist, who enumerated ringworm, impetigo contagiosa, scabies, and pediculosis, and gave his method of treatment and told how important it was to quarantine children with these diseases. He exhibited a case of alopecia areata, which seemed to be of myxœdemic origin, and which had improved under thyroid extract. He also showed a case of pityriasis rubra in a man otherwise very well.

Dr. Micheau said that some cases of these kinds mentioned occurred in the clean, as he had had occasion to notice, and they were very obstinate in spite of every precaution and treatment used.

The Spread of Tuberculosis among the Russian Jews of the City, and Its Prevention.—This was a paper by Dr. J. E. Gichner, who as physician to the Hebrew Benevolent Society of Baltimore had had occasion to observe the great increase of pulmonary tuberculosis in that race, and spoke of the crowded condition of the people and other causes, and outlined plans for its prevention.

This was discussed by Drs. Canfield and Schaffer.

Dr. Charles M. Ellis was elected *President* for the ensuing year.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 20, 1897.

Edward G. Janeway, M.D., President, in the Chair.

Portrait of D. B. St. John Roosa, Ex-President.—Dr. David Webster presented, on behalf of about one hundred physicians, an oil portrait of Dr. Roosa, late president of the academy. Since Dr. Roosa was still with us, the speaker said, perhaps a eulogium would not be in good taste, therefore he would limit himself chiefly to expression of high personal regard for his character and friendship and to reading a few of the letters accompanying subscriptions, all of which testified to marked esteem by the profession. During his presidential term the academy became perpetually exempt from taxation, and the cleansing of the Croton watershed was brought about. He established a precedent which possibly would be ever followed, of declining a second term. In accepting the handsome portrait in the name of the academy, Dr. Janeway expressed again the desirability of adorning the academy walls with portraits of Dr. Austin Flint and of Dr. Alonzo Clark.

Report of Eight Hundred and Five Cases of Sunstroke in New York, 1896; Treatment; Discussion of the Pathology.—Dr. Alexander Lambert read the paper, the latter part of which was a discussion of the pathology of sunstroke by Dr. Ira Van Gieson. The ten days from August 4 to August 14, 1896, would always be remembered as a period in which an extraordinary number of sunstrokes occurred in New York City. The week ending August 15th the total number of deaths in the city was one thousand eight hundred and ten, the largest number ever known since the bureau of vital statistics was established. Of this number six hundred and forty-eight were reported as due to sunstroke. The heat was evidently the cause of this frightful increase in deaths. The total number of deaths from sunstroke for August was seven hundred and twenty-five, and for the year it was seven hundred and sixty-five.

The details of the weather for the ten days of August 4th to August 14th showed, according to the report of Dr. Daniel Draper, Central Park Observatory: Mean hourly humidity for the whole month of August, 73.17, 100 being saturation. For the ten days referred to it was below this mean rather than above it. Therefore the heat was the main factor, which in the shade at Central Park, fifty-three feet above the street, was from 72° to 97° F. August 7th to August 12th, the temperature ranged from 80° to 98° except for about three hours. Of course it was hotter down in the city, or outside the park. The temperature in the sun during working hours of the day averaged 119° F., and ranged from 94° to 137° F. The prevailing wind was a land breeze, from the north and west, below six miles an hour, only one-quarter pound pressure.

To sum up, there was excessive prolonged high temperature, high humidity, this latter being usual here, and absence of cooling breezes. Experience had shown that sunstroke was less common in dry hot

climates than in moist, for evaporation with cooling was more rapid in dry air. High temperature of brief period might be borne, but when long continued caused numerous sunstrokes. The eight hundred and five cases were from the records of Bellevue, Roosevelt, Presbyterian, New York, Hudson Street, St. Vincent's, and the Hood Wright hospitals, and for the statistics the speaker was indebted to Drs. Jackson, Flint, James, Thornley, Loomis, Connor, O'Dwyer, and Knickerbocker. Anything which lessened the resistance of the body to external influences might be said to predispose to sunstroke. The large number of cases in which there was a history of alcoholism was a striking feature. The great majority were alcoholics.

Clinically the cases were divided thus: 1. Heat prostration. 2. The asphyxial or milder form of sunstroke. 3. The hyperpyrexial form. Of the first class there were two hundred and forty-seven. They did not lose consciousness; the temperature did not go above 105° F.; in some it was subnormal. All recovered. Of the so-called asphyxial or mild form there were thirty-eight cases. All recovered. They lost consciousness, but the temperature did not rise to 105° F. There was often a marked predominance of nervous symptoms. Of the third form, hyperpyrexial cases, there were five hundred and twenty cases, with one hundred and thirty-two deaths. All had a temperature of 105° F. or over; only a few retained consciousness. The difference between the three classes was one of degree, not of kind. The majority of the sunstrokes occurred between 2 and 5 P.M. and between 7 and 10 P.M. The nationalities were most diverse. There were no negroes. The occupations were also diverse. Direct exposure to the sun's rays was not necessary, but had occurred in most cases.

The author then considered the symptoms in the three forms. Among prodromes of heat prostration were severe headache, dizziness, pain in back and legs or epigastrium, sometimes numbness and tingling of hands and feet. In some they came on suddenly, in some they were present from one to three days before the patient came to the hospital. In some there were diarrhœa or constipation, nausea and vomiting, and great thirst. The tongue was more often moist and heavily coated. In a few the temperature was subnormal; usually there was a rise from 99° to 104° F. In some after a rest from five to twenty-four hours the temperature gradually returned to normal, and they went out feeling well; the majority continued with slight fever from two to five days.

The second or asphyxial form was by far the least common. The prodromes varied. Sometimes there were none and the patient suddenly lost consciousness. Sometimes this was immediately preceded by dyspnœa or dizziness, or by chromatopsia. In others there were chills, sweating, feeling of fever, diarrhœa or constipation, vomiting. In some there were sensations of pins and needles in the head, or headache. There might be petechial rash on the body, pupils normal or dilated. Unconsciousness lasted until after a bath, or perhaps twenty-four hours. The pulse varied from normal to 140. Its frequency seemed to depend more upon the condition of nervous exhaustion than upon the temperature. The respirations were usually slightly increased, 24 to 28. The temperature did not go above 105° F., was usually lower, sometimes subnormal. Of this class in Bellevue thirty-three were males, five females. The urinary analyses showed no more changes than were usually found in an equal number of alcoholics and normal persons.

In the third or hyperpyrexial class the prodromes when present were often more prolonged, lasting from four to seven days. But there were more histories without prodromal symptoms. Among them were physical weakness, anorexia, great irritability and restlessness, insomnia, nausea, diarrhœa or constipation. Just before consciousness was lost sweating ceased, and there was a feeling of intense heat, a feeling as if the head would burst and eyes bulge out, chromatopsia, blurred vision. Those who had a temperature above 108° F. often had no prodromes. In several cases the patients had kept at work long after noticing anything or answering questions, and finally were taken to the hospital unconscious. In every case in which the temperature was 110° F. or over coma was complete. Those with a lower temperature, if conscious, complained of intense heat and headache. The unconscious patients presented a striking picture—skin dry, hot, and flushed, or cool, pale, and livid, or cyanotic, with clammy perspiration; eyes suffused, or half open, staring, and filmy; pupils contracted, normal, or unevenly dilated; sometimes they would react to light, sometimes not; mouth often open, with lower jaw twitching convulsively; respiration in short gasps, with piteous moan or groan; muscles limp, or twitching convulsively, or in active general convulsion; often wild delirium, struggling furiously; pulse rapid, small, thready, or full and strong with throbbing carotids, or pulseless. In many cases there was a petechial rash on the body and extremities. There was a peculiar disagreeable odor, distinct from the offensive fæces and urine, which often passed involuntarily. Out of the 242 cases with a temperature above 105° F. the temperature in 1 was 117° F., with death; 115° F. in 1, recovery; in 27 it was above 110° F. Of these 242, 167 recovered.

During the bath, or cold pack, or within an hour afterward, about one-half of the patients became conscious, and usually remained so. Many patients did not regain consciousness until next day, or until from three to five days, one not for ten days. Many with temperature above 108° F. did not regain consciousness at all; the temperature was brought down, the pulse remained frequent, dyspnœa and cyanosis were often marked, and they died. These patients usually died within twenty-four hours after admission. Several patients became conscious, later became unconscious again, with delirium, and after from two to seven days recovered, but a few died. Patients admitted in convulsion usually continued to have these after the bath. They were usually a tonic spasm, with intermittent clonic general convulsions. Marked rigidity of the muscles without convulsions was not uncommon. The fall in temperature in the majority of cases was followed by one or more secondary rises, which often required active interference.

The blood showed a decided leucocytosis, red cells distorted, the leucocytes containing pigment. The hæmoglobin color test in twelve cases gave from eighty to one hundred and twenty-five per cent., averaging one hundred per cent., which was far above the normal and was due to the free hæmoglobin in the blood from destruction of the red cells. There was subsequent anæmia in nearly all patients. Some patients spat blood in the bath; a few had bloody stools.

Retention of urine was not uncommon. The urine in the first twenty-four hours semed lower in specific gravity than normal, and to contain a lessened amount of urea. Five to ten days later it seemed of higher specific gravity. Often the urine was normal.

The fatal complications observed were meningitis, pneumonia, acute exacerbation of chronic kidney disease. The cause of death in most cases was failure of respiratory and cardiac centres. In some cases a sudden rigidity of the muscular system caused suffocation. Immediate sequelæ were headache, extreme weakness and malaise, dizziness, soreness, numbness and tingling in hands and feet, extreme anæmia. Three patients became insane with delusional insanity. Two developed inco-ordination of the extremities,

which had remained until now. Dr. Daly had traced seventy-three, after nine months. Of these forty-two had no sequelæ. Three had become insane; twelve had attacks of dizziness and were more sensitive to heat; five had severe headache; one, chromatopsia; one, gastritis; one, changed disposition. Dr. Van Gieson had reported one case in which multiple neuritis and dementia developed two months after sunstroke. There was a peculiar asthenic condition in several cases. Usually within two or three days after the sunstroke the skin had become harsh and dry and finally peeled off. Bruises were common, and hypodermic injections often caused ecchymoses.

Treatment.—The heat prostrations were treated alike in the different hospitals. The patients were put to bed, and if necessary given a cool sponge bath, and phenacetin or some such drug for the headache. This with rest was all that was required. Sometimes an ice cap gave great relief.

In the asphyxial cases tub baths were given at 60° F., or sponge baths, or if their coma and nervous symptoms demanded it they were put for a few minutes into the ice bath and thoroughly rubbed. They required little more than quiet, rest, and stimulation of a cool bath.

It was in the treatment of the hyperpyrexia cases that the test came. Hydrotherapy in some form was tried in all cases. It differed in method of application and temperature of the water. The records of mortality in the different hospitals furnished a fair estimate of the efficacy of the methods employed. The mortality among the patients treated with ice baths, and the bath continued until the temperature had fallen to about 103° or 102° F., varied in the different hospitals from 18 to 27.5 per cent. When in some cases the ice pack was used instead of the ice bath, the mortality was 25.5 per cent. When the ice bath was given for ten minutes, irrespective of the point to which the temperature fell so long as it remained above a safe limit, the mortality was forty per cent. Among patients treated with the bath at from 50° to 75° F. the mortality was one-third. When the baths were given at 90° to 110° F. and reduced in about fifteen or twenty minutes to 72° F., as was done in the Brooklyn Homœopathic Hospital, the results did not seem to be so favorable as with the cold baths. Among the patients treated with a needle spray from a hose attached to the cold-water faucet, the mortality was 11.5 per cent. In St. Vincent's Hospital, in which the treatment was cold packs followed by hot packs, in one hundred and ninety-seven pyrexial cases the death rate was only five per cent., or, counting eight patients who died a week or more later, the mortality was but 9.13 per cent. The death rate of sunstroke as given in Quain's "Dictionary of Medicine" is from forty-one to fifty per cent. In the entire number of hyperpyrexia cases, as recorded in this paper, five hundred and forty, the death rate was 25.38 per cent. Therefore the treatment employed in the various city hospitals had given very satisfactory results.

The author gave in greater detail the bath treatment, and said the ice bath was one in which the patient was placed in a tub with crushed ice. It was emphasized that the stay in the bath was accompanied by very vigorous rubbing by several attendants. The ice pack was given by placing the patient on a rubber sheet and putting ice along the legs and body, and rubbing with ice. The author did not think favorably of it. The needle spray was given in the Flower Surgical Hospital, patient on a rubber sheet, ice cap on the head, three streams playing over him from cold-water faucets. The results were good. In St. Vincent's, where they got the best results, the method consisted in dashing water on the patient from pitchers at a distance, the patient lying on a cot, rubber under him, wrapped in cotton sheets. Drugs had little effect until the temperature had been reduced. Nitrite of amyl, one or two drops in the nose, sometimes relaxed muscular spasm and convulsions.

Briefly, the best treatment seemed to be a needle spray, or ice bath, or cold pack till the temperature fell to 103° or 104° F., followed immediately by a hot pack, with stimulants and sedatives as one's judgment might deem necessary.

Pathology.—The gross pathology of sunstroke had always been conflicting, and the changes found not characterized by any definite and uniform lesions, and it seemed that we must finally turn to cellular pathology, to study the changes in the cells themselves, in order, if possible, to discover both cause and effects. The prodromal symptoms were those of acute functional disturbances, and the serious later symptoms showed that there were grave changes in the blood and in all the nervous centres, especially those which held in a state of equilibrium the heating mechanism of the body. Dr. Ira Van Gieson had furnished him a preliminary report of the changes in the nervous system in fifteen cases of sunstroke.

Sections had been examined from the spinal cord, cerebellum, and various portions of the cerebrum. All showed more or less changes in the chromophilic plaques of the ganglion cells. These plaques in some cells were changed in shape and were fewer in number; in some they appeared to be broken up or to have entirely disappeared. Since the chromophilic plaques showed the potential energy stored in the cells, and any changes in the nucleus might be said to be directed against the life of the cell, it would readily be appreciated how extensive were the changes which had occurred. Dr. Van Gieson's deductions were: In three cases referred to there was universal exhibition of acute parenchymatous degeneration of the neurons of the whole neural axis. In the brain cortex and in the cerebellum the cells showed the same stages of degeneration. The spinal-cord cells were apparently not so extensively involved. There seemed to be no other interpretation open as to the significance of this degeneration than the operation of a toxic substance upon the ganglion cells. There was, in other words, a toxic cytolysis in insolation, or cell resolution of the neurons, which depended upon the condition of the body forces, the eliminative capacity of the body, and the duration of the poison. Depending on these three factors, the neural parenchymatous degeneration might result in restoration or destruction of the neurons involved.

This theory that sunstroke was an auto-intoxication with heat as a contributing cause, and not the direct and only cause, was not new. The blood serum from the bleeding of some patients when injected in doses of only five cubic centimetres caused death in rabbits within an hour. The urine at the time of admission was markedly less toxic to animals than twenty-four hours later, seeming to show retention of the toxic substances in the body at the time of the sunstroke. But these experiments had been few in number, and it could not be claimed that the auto-intoxication theory had yet been fully proven. Heat alone, however, did not seem sufficient to explain all of the clinical and pathological observations.

Dr. Ira Van Gieson opened the discussion, and further elucidated his views as to the pathology stated above, and spoke of the experiments on animals. Regularly a certain number of these patients made their way to the insane asylums. His studies in one case of multiple neuritis and dementia had been mentioned in the paper.

Heavy Clothing and Sunstroke.—Dr. L. A. Connor gave his experience in one of the hospitals. He had recognized only two classes of cases of sunstroke in

patients who entered there: 1. Heat prostration, sometimes temporary loss of consciousness, temperature slightly elevated, sometimes subnormal. 2. Cases of real sunstroke, though varying still in degree. He agreed with Dr. Lambert, that vigorous and constant rubbing should be used during the bath. At his hospital the mortality had been about twenty-seven per cent. Dr. Connor dwelt on prophylaxis, pointing out the great proportion of cases in which the patient had worn heavy clothing in spite of the intense heat. The hat was usually black and heavy. He thought the board of health might wisely distribute circulars of information, warning against too heavy clothing in hot weather. The reflection from the sidewalks dazzled the eyes, and it might be well to wear green spectacles.

Dr. J. P. Thornley said that at the Presbyterian Hospital they had recognized about two practical classes, those of prostration and those of genuine sunstroke. The treatment had been the tub bath, temperature of 40° F. The results had been fairly good. With one exception the patients who recovered recovered completely. One had symptoms of meningitis.

The Heat Regulating Theory.—Dr. L. F. Bishop presented his views as follows:

"We have all listened with pleasure to Dr. Lambert's interesting paper and the instructive remarks of those who have followed him. It would seem that there is not very much to add as to the statistical part of the subject, nor is there much to suggest in the line of therapeutics. However, the experience of last summer and the discussion of this evening have given rise to some thoughts which, though perhaps in the field of medical philosophy, will not be out of place.

"Whatever may have been said as to the mechanism of sunstroke, it would seem that the old explanation would still be most worthy of belief—that the body, after being subjected for a long period of time to a high temperature, becomes exhausted as to its power of heat regulation. The heat-producing forces in the body are always in excess of the requirements of economy. Now, during health the heat-controlling forces keep the temperature within bounds, but when these forces have been put on the strain for a long period of time they may at some particular time give out, and the temperature of the body rise to an enormous degree, as in sunstroke. It may, of course, be true that the heat-producing forces in the body are very much increased under the stimulus of external heat, but the essential element in the production of sunstroke is the failure of the heat-controlling forces.

"There is another point suggested by the study of fever in general, and thermic fever in particular, and that is that fever is not a positive quantity but a relative quantity. The normal temperature of the body is maintained by a balance between the heat-producing forces and the heat-controlling forces. Now it is very evident that in certain individuals at certain times the heat-producing forces may be very low and the heat-controlling forces correspondingly inactive, while in others at other times the heat-producing forces may be very active, but the heat-controlling forces may still be adequate to maintain the normal temperature. In either case the temperature of the body would be 98.4° F., but the actual conditions presented would be very different. Hence there is a fallacy in believing that we can estimate the thermic condition of the body by the measurement of a thermometer. Fever, as a rule, indicates weakness; but likewise a low temperature may indicate weakness. For instance, in the high temperature of pneumonia, we have in abeyance the heat-controlling forces, allowing the temperature to rise under the stimulus of the disease. In defervescence with collapse in the course of pneumonia, we may have a failure of the heat-producing forces simultaneously with the re-establishment of the heat-controlling forces, producing a condition of depression more dangerous than the high temperature.

"I had not intended to speak of therapeutics, but there is one point in connection with the cold-water treatment of sunstroke that has emphasized what has previously seemed to be true with the cold-water treatment of typhoid fever, namely, that the procedure has a value beyond that of the actual reduction of temperature. It seems to have the power of re-habilitating the heat centres and giving them the power of taking up their work in their proper way.

"The value of the study of sunstroke in these latitudes must have an importance of its own. The effect of climate upon the constitution of the population is such that we cannot draw our conclusions from the results of lower latitudes. People living in the south and going north are able at first to stand low temperatures remarkably well. The same is true of people going from the north south as to high temperature, but after a time each must adopt the customs of the country to which he has gone.

"In conclusion, we would like to emphasize our belief that sunstroke is in the category of physiological rather than chemical or bacterial disorders, and that whatever substances have been found are the results of the high temperature, which was primarily due to a functional derangement of the heat-controlling and heat-producing forces. The condition of sunstroke may be closely imitated by hyperpyrexia in any acute disease. In rheumatism, or even in typhoid, there is a high temperature existing from internal causes, which may bring about the same catastrophe to the heat centres as if produced by external heat of the atmosphere. Sunstroke is a disease of the nervous system.

"The lower grades of thermic fever have not been considered particularly, because the subject, sunstroke, has hardly suggested their study; but it should be borne in mind, especially as to young children in the large cities, that thermic fever may resemble very closely cholera infantum, and that it may exist entirely independent of any primary digestive disturbance. In these cases, of course, laboratory milk is not a panacea.

"We must all feel indebted to Dr. Lambert for bringing this subject before us at this time. We hope that we may not have an opportunity this summer of putting our mature knowledge to practical use, as we had last summer."

The Benefit of Mechanical Irritation of the Skin.—Dr. Simon Baruch said that the benefit derived from the various ways of using water was not due so much to the cold as it was to the mechanical irritation of the cutaneous nerves. That fact should be borne in mind in all cases of application of cold to the surface. All hydrotherapists advised friction of the skin in combination with cold water.

Would Hasten the Erection of Public Baths.—Dr. Baruch offered a resolution, urging the city authorities to proceed with the erection of city baths as had been provided for by legislative enactment. The resolution was laid over, under the rules, until the next meeting.

Tuberculosis.—For the cure of tuberculous disease of the lungs, as we ordinarily meet it, we need a specific for pyæmia quite as much as one for tuberculosis, for in most cases there is mixed infection, and when the disease is well advanced the pyæmia is as marked as the tuberculosis. Moreover, while the human system can often vigorously resist the tubercle bacillus, it usually fights a losing battle against the combined attack of it and pyogenic organisms.—W. S. Davis, *Medicine*, April, 1897.

Therapeutic Hints.

Atonic Ulcers.—

℞ Iodol ..... 2 parts.
Vaseline,
Lanolin ..... āā [illegible]
M. Spread thin on aseptic lint and apply.

—*La Presse Médicale.*

Cough Mixture.—

℞ Ext. pruni virgin..... ℥ i.
Aq. camphor..... ℥ vij.
Glycerin. ..... ℥ i.
M. S. Teaspoonful every two to four hours.

—B. F. Sherman.

Chronic Rhino-Pharyngitis.—

℞ Menthol..... 1
Oil of sweet almonds, or
Liquid vaseline 10
Apply locally with a brush.

—Hamon de Fougeray.

Intestinal Antisepsis.—

℞ Naphthol (alpha) ..... gm. iij.
Chloroform ..... gtt. xv.
Castor oil ..... gm. c.
Oil of peppermint ..... gtt. v.
M. S. A tablespoonful in port wine, beer, or black coffee with sugar, for adults, and a teaspoonful for children.

—J. de Maximowitch.

Cancer of the Uterus.—

℞ Sodii chlorat..... ℥ v.
Syr. aurant. flor..... ℥ i.
Aq. dest. ..... ℥ iij.
M. S. From two to eight teaspoonfuls to be taken daily.

Locally:

℞ Sodii chlorat,
Bismuth subnitrat .....āā ℥ iiss.
Iodoform..... ℥ i.
M. S. Apply a small quantity on a tampon to the cervix.

—E. Duvrae.

Acute Localized Prostatitis.—

℞ Iodoform,
Extract of hyoscyamus.....āā gr. ss.
Cacao butter..... gr. xlv.
M. S. Use as a suppository.

—*Journal des Praticiens.*

Lumbago.—

℞ Atropine..... gr. iv.
Oleic acid..... ℥ i.
Castor oil ..... ℥ i.
Oil of lavender ..... ♏v.
Rectified spirit. .....q.s. ad ℥ i.
S. For local application.

—Martindale *and* Westcott.

Chronic Rheumatism.—

℞ Potassii iodidi..... ℥ iij.
Vini colchici sem.,
Tinct. opii camph... .....āā ℥ ij.
Tinct. stramonii ..... ℥ vi.
Tinct. cimicifugæ..... ℥ iij.
M. S. A teaspoonful thrice daily.

—*St. Luke's Hospital, N. Y.*

Furuncles of the Eyelid.—

℞ Tincture of camphor,
Precipitated sulphur.....āā gr. xv.
Lime water,
Rose water .....āā ℥ iiss.
Gum arabic..... gr. iij.

—Landolt *and* Gigax.

Tympanites.—

℞ Ol. terebinthinæ ..... ℥ i.
Ol. amygdalæ dulc ..... ℥ ss
Tr. opii..... ℥ ij.
Mucil. acaciæ..... ℥ v.
Aq. laurocerasi..... ℥ ss.
S. A teaspoonful every three to six hours.

—*Medical Press and Circular.*

Correspondence.

OUR LONDON LETTER.

[From our special Correspondent.]

ROYAL COLLEGE OF SURGEONS—COUNCIL ELECTION—FELLOWSHIP EXAMINATIONS—MEDICAL-AID ASSOCIATIONS—ANNUAL MEETING OF FELLOWS—MEMBERS' CLAIMS REJECTED—MR. ANDERSON'S APPEAL—GARBAGE AND ELECTRIC LIGHTING—EPILEPTIC COLONIES—BIRMINGHAM HOSPITAL AND ROYALTY—HOSPITAL REFORM—SIR J. REID—HEALTH OF LONDON.

London, July [illegible], 1897.

The election to the council of the College of Surgeons came off last week. Mr. Howse and Dr. Ward Cousins were re-elected for another term, and the three new members are Messrs. Edmund Owen, Rickman Godlee, and Watson Cheyne. The election was not more exciting than usual since voting-papers came into use; forty-six fellows voted in person, six hundred and nine by proxy, four votes were invalid, and four were too late. It is to be feared that reformers have little reason to congratulate themselves on the result. The new members are not particularly liberal in their views, so far as their public statements show, and assuredly all three cannot compensate the cause of progress for the loss of the late Mr. Rivington.

As to other college matters, the examination for the fellowship is being discussed again, and no wonder, for it is the most uncertain of all the examinations. Neither teachers nor candidates can form any opinion as to the chances, and both are naturally very dissatisfied. The new members might very well take up this question, which as teachers they have good opportunities of understanding.

Another question relates to the powers of the council to censure members. The bylaws allow the council to remove from the list any fellow or member judged by the council to be guilty of disgraceful conduct in a professional respect. Some are anxious this power should be brought to bear on those who accept situations under the medical-aid associations. The council has referred this question to its legal advisers, and has not expressed any opinion of its own on the matter and evidently prefers not to do so. It will not surprise me if the lawyers advise against the exercise of the power of expulsion, as it is quite possible such a course might lead to litigation, and it is at least doubtful whether the judges would uphold such a power for such a purpose or pronounce it as "in restriction of trade." Perhaps a milder course would be more effectual. The council might surely have the courage of its opinions, and let every one know whether it considers these so-called aid associations injurious to the profession, and accordingly whether holding office under them is discreditable to members of the college.

The annual meeting of the fellows was held on Monday. The question whether members should be allowed any voice in their college was, you may remember, put to the fellows for an expression of opinion by circular. The papers have been returned, and two hundred and one fellows have declared for this measure of justice, but two hundred and eighty-four voted against giving up any share of their exclusive privileges.

Mr. Anderson's case came before the meeting, the council having declined to contribute to the fund for his appeal to the House of Lords. Mr. Anderson pleaded his claim to assistance on the ground that the college undertakes to protect fellows and members in the exercise of their profession. The president, Sir William MacCormack, replied that the college funds

were a trust committed to them, and that the museum showed how well the trust had been fulfilled, and although sympathizing with Mr. Anderson and willing as individuals to subscribe to a special fund, the council did not feel justified in using the corporate money for the purpose.

The conclusion seems as lame as the premises, for the college thus refuses to maintain the rights of its fellows and members, either by initiating proceedings in the courts or subscribing toward law costs. The fellows, however, indorsed the conclusion by twenty-five to four votes, though a number of them did not vote at all. The question involved is a most important one, and the Civil Rights Association has taken it up with energy, but funds are needed for carrying on the contest. Perhaps no greater perversion of justice has been brought before the public. Mr. Anderson's prosecution was at the hands of the judges in Tobago, and the doctrine that the judge is not liable for malicious actions done in the capacity of judge must be set aside before justice can be done to Mr. Anderson. Hence the question at issue is important to every citizen, and the protection of civil rights a cause worth fighting for.

The utilization of waste products has a natural charm for the sanitary reformer, who sees in the process a means of getting rid of noxious material more effectual than its removal at considerable cost. The "dust cart" has long been a source of vexation to every citizen, but there is a promise of the dawn of better days. Shoreditch vestry leads the way, and last week Lord Kelvin presided at the opening ceremony of the new works erected for that part of the metropolis. The garbage of the dust carts is to be utilized as fuel for the engines which drive the dynamos for electric lighting. If not the first attempt, this seems to be the first success scored in this line, and to be partly due to a system of storing the heat so that it can be used by night, when it is more needed than by day. Lord Kelvin, who should know, said the plan was an example of the amalgamation of scientific knowledge and forethought with mechanical engineering and skill. Perhaps West End vestries will now follow easterly Shoreditch.

The committee of the National Society for the Employment of Epileptics is appealing for funds to enable it to carry on its excellent work. It has indeed money in hand for special enlargements and new homes, but the general finances are at a low ebb. The colony has passed beyond the experimental stage; it would be a calamity to discontinue it. The patients are taken from the bad hygienic surroundings of towns, and employed in gardens, fields, orchards, and workshops in the country, where they have an abundant simple diet without alcohol. A marked improvement is generally noticed soon after admission. I think you have a similar system in working order in the States, and you will be glad to hear that it is successful here.

On Wednesday the Princess Christian with her husband and daughter went to Birmingham, to open the new buildings of the General Hospital in the name of her mother, the Queen. The city received the royal visitors with great enthusiasm, and the princess expressed gratification at the success which had been secured to the hospital and her own great interest in the sick poor.

The Hospital Reform Association carried its resolution at Bristol, although there were not wanting some differences of opinion as to the method of removing admitted abuses. It seems an excellent plan of this vigorous young society to visit the several towns where there are large hospitals, and get the local members of the profession to discuss the subject.

Sir James Reid, K.C.B., resident physician of the Queen, receives the additional honor of a baronetcy, and every one seems pleased that his services are thus recognized. One or two additional honors have also reached our colonial brethren, and also given satisfaction. On the other hand, there is some grumbling at home. It is felt that the profession might well have received further distinctions on so important an occasion. Why should Irish presidents get knighthood, and English baronetcies? I was prepared to hear this question, for, whatever Ireland gets, she asks for more. I was, however, scarcely prepared for the Scotch grumble, which the lay press has indorsed. Scotland has generally had full appreciation, although the Scottish colleges are omitted. After all, this talk of the different kingdoms in such matters partakes of the parochial.

The phenomenal health of the metropolis is maintained. In the last week the mortality returns fell further to 13.5 per 1,000. The last four weeks the figures have been 13.8, 14.6, 14.6, and 13.5, showing an average for the month of 14.1, which is 3.1 below the average for the decade, corrected for increase of population.

OUR BERLIN LETTER.

[From our Special Correspondent.]

THE FIFTEENTH GERMAN CONGRESS OF INTERNAL MEDICINE.

BERLIN, July 1, 1897.

THE fifteenth congress of internal medicine, which was held recently, was satisfactory throughout. The interest taken by the members was a very active one, and the arrangement introduced of having demonstrations on certain days only was an eminently practical one. Provision was also made for the entertainment of the members in the shape of a festive performance at the opera house and a festive banquet in the Zoölogical Garden.

Professor Leyden was absent from the city at the time, and in his place Professor Schmidt, of Frankfort, opened the congress with an address of welcome. Following this Professor Bäumler read a paper on "Chronic Articular Rheumatism and its Treatment." He dwelt upon the history of the term rheumatism. Originally employed as denoting a mucous flow, it later became a general term for all "colds" and their sequelæ. An especially important form of rheumatism is "polyarthritis deformans," in the study of which the Roentgen rays have proven of great value. The speaker summed up as follows: Only uncomplicated cases should be classed as "chronic articular rheumatism;" bacteriological researches have shown it to be very probable that it is of bacterial origin. It is to be remembered that in its course various damaging influences are working upon the patient at the same time.

Dr. Ott spoke upon the general treatment of chronic rheumatism. He believed the best results are to be obtained from hygienic methods: the careful provision for fresh air, good and proper clothing and nutrition, and suitable bathing.

In the discussion the main interest centred itself about the question: Is or is not articular rheumatism an infectious disease? The first to speak was Professor Chvostek, of Vienna. He had examined the blood and joint fluid of rheumatics, and had made experiments upon animals, but all with negative results. He therefore regarded articular rheumatism in no sense as due to an invasion of the joint by bacteria. He looked upon it rather as a toxic process. The swelling of the joints is caused by a toxin; the condition of the joints makes it easy for bacteria to lodge

and propagate there, but this is of but slight importance—a mere side issue.

Dr. Singer, of Vienna, held that chronic articular rheumatism is of bacterial origin. He based his opinion principally upon the finding of the staphylococcus in the joints. He believed there is no single germ, but a number of various germs causing the disease.

Professor v. Noorden had investigated the popular "lemon cure" of the laity. He found there was no alteration in the metabolism caused thereby, but no patient was improved by it. He believed that a regular steady reduction in weight was beneficial. He had found the Roentgen rays of decided advantage in the study of articular rheumatism and similar disorders.

Bäumler, in closing the discussion, said that the bacteriological question was the one toward which special attention would be directed in future studies of chronic articular rheumatism.

On the second day of the congress Professor Behring, the discoverer of the diphtheria antitoxin, addressed the assemblage, by special request, upon "Etiological Therapeutics as Founded upon Experiment." Owing to improved methods in the preparation of the antitoxin, it is now possible to exclude the adventitious products which are the cause of the injurious effect of antitoxin preparation. Antitoxin in itself is harmless; it acts exclusively upon the specific poison present in the body. It has not been possible heretofore to produce it in uncontaminated form, but the speaker did not think this necessary. It requires the passage of the toxin through an animal body to produce the antitoxin. A strong tuberculosis antitoxin has been recently prepared in Marburg, and it is expected that practical results will follow its use. We have thus the prospects of obtaining a good working tuberculosis antitoxin.

Dr. Boas, of Berlin, presented a case of peristaltic restlessness of the stomach and intestines. These organs were in constant visible motion, and yet the patient felt herself otherwise entirely well.

Prof. Albert Fränkel discussed the surgical treatment of hydrops pericardii. He pleaded for the opening of the pericardium through an incision, and condemned simple puncture as dangerous. He showed a child who had had a pericarditis, and had been completely cured by a radical operation.

After a number of demonstrations and short addresses, Dr. Magnus-Levy read a paper on "Myxœdema and Sporadic Cretinism," two closely related diseases. He found the metabolism in them diminished, a circumstance in striking contrast to Graves' disease, in which it is increased.

Professor Kronecker, of Bern, reported his conclusions from a study of paralysis of the heart alleged to follow obstruction within the coronary arteries. He held that such a paralysis does exist.

Professor Langerhans, of Berlin, presented the organs of a young man who had been treated with Koch's newest tuberculin and who subsequently died. Autopsy showed a general miliary tuberculosis; the condition reminded one strongly of that found after the employment of Koch's original tuberculin.

Professor Rumpf, of Hamburg, said that, in spite of extensive employment of the new tuberculin, he had never seen any disastrous result.

Professor Liebreich, by special request of the congress, next spoke at length of the "Modern Medicinal Therapy." He was strongly opposed to Behring's school and its methods, and classed himself with the old school. He regarded the excitors of tuberculosis as parasites, which thrive and propagate upon any proper soil. He was opposed to the recognition of a bacterium as the cause of an infectious disease. Especially did he oppose orrhotherapy. He recommended cantharidin in the treatment of tuberculosis, claiming for it that it increases the vitality of the cells.

After the applications of the Roentgen rays in internal medicine were discussed, the question of lumbar puncture was taken up. This procedure, introduced by Quincke, was discussed by that authority as well as by Lenhartz and Fürbringer, these three being best qualified to comment upon it. A diagnostic value attaches itself to the method, especially in tuberculous meningitis. It is hardly to be expected that it will be employed in regular practice, owing to the difficulty of the operation.

Dr. Goldscheider read a paper on the "Effect of Irritations in the Pathology and the Therapy of the Nervous System in the Light of the Neuron Theory." The neuron theory opens to us new views and ideas in the teaching of psychology and nervous disease. Briefly put, it regards each cell with its axis cylinder as constituting a formative and nutritive unity. Irritations must have a certain degree of intensity, in order that they may pass from one neuron to its neighboring one. All neurons are associated, yet each one has its own irritability. The neuron theory explains the symptoms of hysteria, neuralgia, hyperæsthesia, tachycardia, etc.

ORRHOTHERAPY OF TUBERCULOSIS.

To the Editor of the Medical Record.

Sir: Allow me to reply briefly to certain strictures of Dr. Rochester (Medical Record, p. 58) on the use of serum in tuberculosis. Dr. Rochester used the serum in cases against which he was expressly warned—cases of mixed infection, practically moribund, and acknowledged by himself to have been unsuitable. Dr. Rochester disregarded instructions in the use of the serum, and so his report was unscientific.

Paul Paquin, M.D

St. Louis, Mo.

PAY FOR HOSPITAL ATTENDANCE.

To the Editor of the Medical Record.

Sir: I have read with interest the editorials in the Medical Record dealing with the abuse of charity in the hospitals and dispensaries of this city. Remedy after remedy is suggested, but, strangely enough, the only effective one is ignored. Abuse, varying in degree, is heaped upon boards of managers, and philanthropists are scored because they wink at the misuse of public and of private funds which go to the support of these institutions. The chief culprit, however, is overlooked, and this culprit is the doctor himself. Take any one of these institutions, and you will note that, from the superintendent to the scrubwoman, all are salaried. The prime essential agent in the running of the institution secures nothing but experience. Now the doctor is much like his fellows in other walks of life: he cannot feed himself, nor wife nor children, on experience; and yet, day by day and year by year, we see him giving time and skill without pay for humanity's sake—true enough, but, as has been amply proven and as will be more fully certified, to human beings fifty per cent. of whom are able to pay. Now the remedy is so plain that as I write I feel that I am offering an insult to intelligence. Let the profession decline as a unit to serve gratis in any hospital or dispensary except those conducted by the city for the care of the paupers. The poor would then be cared for, while those of moderate means and the well-to-do would have to pay, since all institutions not conducted in the spirit of proper charity would have to close their doors for lack of the mainspring—the doctor.

It is the duty of the city to care for its indigent. The city should establish in each ward a hospital and a dispensary, where the poor of the ward could resort. One or more salaried agents could keep track of the applicants, even as the registered voters are traced. The doctors in each ward would gladly treat these paupers, and thus gain experience without robbing themselves and their colleagues, and without, as under the present system, teaching the rich and well-to-do how to pose as paupers when sickness strikes them.

EGBERT H. GRANDIN, M.D.

New Instruments.

A METAL DOUBLE-CURRENT RECTAL IRRIGATOR.

BY ROBERT COLEMAN KEMP, M.D.,

NEW YORK.

THIS instrument is made after the same model as the hard-rubber tube—a central tube opening at its apex and two lateral openings in the outer tube. It is five inches long, is nickel plated, and is as cheap as the rubber instrument. There are several sizes made, No. 4 being the best. The cap and central tube unscrew in a single piece. The tube is durable and can be boiled. In using high temperatures of fluid, a small collar of soft-rubber tubing can be slipped over it, to protect the sphincter from the hot metal. The instrument is made by Reynders & Co., New York.

449 PARK AVENUE.

A NEW DYNAMOMETER.

BY T. J. McGILLICUDDY, M.D.,

NEW YORK.

IN chronic abdominal and chest disorders the use of anthropometric instruments is very necessary, to show

FIG. 1.

the gradual gain in flesh and strength or the diminution of fat that takes place during the course of treatment. Regular records of these measurements should be carefully kept. The ordinary or Mathieu dynamometer, which is a modification of the Regnier, has been used, not only for measuring the strength of the hands, but, by attaching special handles, straps, holders, or frames, the strength of other portions of the body, such as the chest, back, forearms, and legs, has been obtained. These holders or frames are rather complicated and bothersome, and look as though they might readily get out of order. They cost as much as the new instrument which I have devised. Some years ago I had this circular spring dynamometer made by Messrs. Tiemann & Co., and to it I have had handles attached, which give sufficient room for the insertion of the foot when testing the strength of the side of the body, as in Fig. 3. This instrument can also be used to test the strength of the forearms, chest, and back. The illustrations show the method of using it in testing the strength of certain groups of muscles. Those engaged in the treatment of chronic diseases

FIG. 2.

FIG. 3.

will find this dynamometer of practical value for gradual strength measurements. It combines simplicity with cheapness, is light and convenient, and is made to register two hundred pounds or more. Both the English and metric systems can be used. It is carefully tested and is absolutely accurate.

Long-Lived Women.—Of the thirty-five centenarians in Massachusetts, thirty are women.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 17, 1897:

	Cases.	Deaths.
Tuberculosis	112	115
Typhoid fever	22	8
Scarlet fever	97	11
Cerebro-spinal meningitis	0	9
Measles	179	10
Diphtheria	151	27
Laryngeal diphtheria (croup)	6	2
Chicken-pox	10	0
Small-pox	1	1

The Intelligent Compositor.—Ours is a marvel. We wrote: "Is there no balm in Gilead?" Supposing we didn't mean it, or were mistaken in the town, our compositor slung it up "Goliad." But that's a small matter. Some years ago, in compiling a mortuary report from exchanges, we wrote: "Dr. Jno. B. Bailyhache, *et.* 74 years, born July 20, 1822, and died —." Imagine our consternation on finding the proof sheets to read: "Dr. Jno. Bellyache eat 74 ears corn July 20, 1822, and died —."—*Texas Medical Journal.*

The Helpful Hen.—In China the hen is kept constantly busy. When not engaged in hatching her own brood she is compelled to hatch fish eggs. The spawn of fish is placed in an eggshell, which is hermetically sealed and placed under the unsuspecting hen. After some days the eggshell is removed and carefully broken, and the spawn, which has been warmed into life, is emptied into a shallow pool, well warmed by the sun. Here the minnows that soon develop are nursed until strong enough to be turned into a lake or stream.—*Medical and Surgical Reporter.*

Beer Drinking and Longevity.—Insurance doctors are much against beer drinking. Dr. Rogers, of the New York Life, in reference to beer, says: "Recently I had occasion to make some study of what happens among persons engaged in the manufacture of beer. My cases included not only the workmen engaged in breweries, but also the proprietors of breweries. It is a curious fact that the mortality among the proprietors is about as high as among the workmen, showing that they are all given to copious libations. The mortality is strikingly low among brewers in early years. Up to forty or thereabouts, brewers seem to be about as good risks as pretty much anybody else. After forty the mortality rises very high, and I should say that at fifty-five or sixty years of age about three brewers may be expected to die where one average person dies."

Training the Nervous System.—At a recent meeting of the Naturalists' Society in Dundee, Dr. Rorie read a paper on this subject, which is referred to in *The Lancet* as follows: "Can the functions of the nervous system be raised by care and steady diligence to a higher standard than would appear at present to hold ground? In other words: Could the present mental and moral standard of the human subject be raised by the improvement and education of the nerve cell; and, secondly, would mere neglect in the regular exercise of the various nerve centres—allowing these to sink into a state of atrophy—result in moral and intellectual degeneration? In elaborating his theme, Dr. Rorie proceeded to give a lucid explanation of recent additions to the knowledge and functions of the nerve cells, illustrating his remarks by means of a large series of diagrams; their structure and development and the importance of a healthy nutrition were fully explained. It was also pointed out how periods of mental depression and barrenness and states of activity and fruition were in their turn to be traced to the exhaustion and recuperation of the nerve cells respectively. The condition of the nerve cell in relation to the development of insanity and its bearing upon the elucidation of many most important points connected with criminal anthropology were touched upon. In conclusion, Dr. Rorie stated that the latent capacities of individuals were in the majority of cases, if not in all, far beyond what are usually reached, and that the possibilities of increasing and developing these to their full extent depended on raising the vitality of the nervous system to its highest degree. In every individual vast numbers of cerebral cells probably remained undeveloped, and although as yet no nerve centres had been found corresponding to our knowledge of good and evil, of justice and benevolence, of purity and veracity, it could hardly be doubted that these had correlative neural equivalents equally with the mental and intellectual faculties, and they were therefore as much worthy of careful training."

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service during the week ended July 17, 1897:

SMALL-POX—UNITED STATES.

		Cases.	Deaths.
Memphis, Tenn.	July 3d to 10th	2	
New York, N.Y.	July 3d to 10th	..	1
Toledo, Ohio	June 1st to 30th	4	1

SMALL-POX—FOREIGN.

Glasgow, Scotland	June 14th to 20th	1	
Madrid, Spain	June 16th to 23d	..	4
Pernambuco, Brazil	April 25th to May 29th	..	17
Sagua la Grande, Cuba	June 26th to July 3d	80	3
Havana, Cuba	June 1st to 30th	..	9
Warsaw, Russia	June 19th to 26th	..	4
Odessa, Russia	June 19th to 26th	4	
Zurich, Switzerland	June 14th to 20th	4	
Manaos, Brazil	June 12th to 26th	103	52
St. Petersburg, Russia	June 14th to 26th	8	1
Matanzas, Cuba	June 23d to July 7th	..	2
Hong-Kong, China	May 22d to 29th	..	2
Osaka and Hiogo, Japan	June 5th to 12th	1	
Montreal, Canada	June 25th to July 2d	2

THE POSSIBLE MORPHOLOGICAL BASIS FOR SOME DISEASES OF THE LUNG.[1]

BY WOODS HUTCHINSON, A.M., M.D.,

[illegible], N. Y.,

[illegible] OF COMPARATIVE PATHOLOGY, UNIVERSITY OF [illegible]
[illegible] DEPARTMENT.

IT might at first sight appear almost inappropriate to introduce the consideration of pathological problems in an association of anatomists *pur sang*, but an explanation of the real meaning of my title will, I think, indicate its right to appear upon the programme. The aim of the paper is not to inject pathological considerations into anatomy, but if possible to inject a little anatomical spirit, and the order and rationality that go with it, into the at present sadly chaotic realm of pathology. In other words, it will be a perhaps presumptuous endeavor to prove that we have, in some cases at least, a valid morphological basis for disease; that disease, being but life out of place, vital energy gone wrong, has its laws, its ancestry, and its principles of development as certainly as health has. And it is my firm personal conviction, now that the wonderful impulse which the oil-immersion lens and the bacteriological world opened up by it to our view have given to pathology has apparently reached its flood, and even shows some tendency to subsidence, that the chief hope of advancing and systematizing our knowledge of disease and explaining some of its deepest problems lies in the anatomist in general, and in the comparative anatomist in particular, rather than in the bacteriologist or the pure pathologist. I may make these remarks with all the better grace from the fact that I can hardly claim enrolment in either of the great armies that have been mentioned, and can only venture to approach the subject from the standpoint of a clinical pathologist, both human and comparative, with the hope that the few fragmentary connections which appear to suggest themselves to my mind, between the processes of development and those of disease, may be taken up and adequately discussed and enriched by further illustration by such a body of experts as this.

The suggestions which I would like briefly to present for your discussion will be along the following lines: First, as to the vulnerability of the organ or organs in question, as contrasted with other organs of the body; second, what explanation for this comparative vulnerability or immunity, as the case may be, may be found in the ancestry of the organ itself; third, in what particular region of the organ, if any, is disease most likely to occur, and what are the relations between this local liability and the development of the part; and fourth, as to the nature of some special lesions which occur, and their possible relation to ancestral tendencies. The first thing that strikes us, at even a most cursory glance at vital statistics or bills of mortality, is the "bad eminence" occupied by diseases of the lungs as a cause of death. In the first place, we have from thirteen to nineteen per cent. of the entire number of deaths due to pulmonary tuberculosis; and in the second place, the next most prominent feature in the list will be found to be the so-called "inflammatory" diseases of the organ, as pneumonia, bronchitis, influenza, etc. In fact, by adding together the various forms of diseases of the lung, which appear in the death records, in the human species, it will be found that they are responsible for at least twenty-five per cent., and, according to some observers, thirty to thirty-three per cent. of the entire mortality. I do not quote figures, simply because these facts are matters of general knowledge, or if not can be verified in fifteen minutes by any who will take the trouble to turn to the mortality records of any of our large cities or States. Nor is this state of affairs confined to the human kingdom. Definite statistics as to the actual morbility from any cause are of course practically impossible of attainment from our near cousins, the domesticated animals, for the reason that, first, no systematic record of deaths is kept, and, second, that so comparatively few of them, outside of horses, die from natural causes; but such records as we possess seem to point to an almost precisely similar state of affairs in them. For example, such diseases as pleuro-pneumonia in cattle, epizoötic in horses, tuberculosis in horned cattle and in birds, and one of the most fatal forms of hog cholera, are all of them of this nature. Of tuberculosis alone we possess some sort of record, and it ranges, according to the observer, from an average of fifteen per cent. to twenty-five per cent. in the French and English dairy cattle, to as high as the almost incredible proportion of seventy per cent. in the Holstein-Friesians. That is to say, of cattle used in the dairy, anywhere from twenty-five to seventy per cent. are said to contract pulmonary tuberculosis at some time during their lives.

As to the undomesticated animals, in a state of nature, little of course is known, partly from the lack of observation and partly because their carcasses are pounced upon by some one of a dozen scavengers, eagerly anxious for a meal. But the records of those specimens kept in captivity, either as pets or for scientific purposes, support this position. It is stated that from eighty to ninety per cent. of monkeys die either of tuberculosis, bronchitis, or pneumonia. The canines and felines in spite of their normal immunity from tuberculosis, which will be discussed later, fall under the same ban and are extremely liable to die of pneumonia or bronchitis. Among the ungulates generally the rule does not hold to quite the same degree, but that I believe, to put it roughly and somewhat Hibernianly, is because they die of alimentary disorders before they have time to develop the slower and more chronic lung diseases to which they are so specially liable. Nor can we find any great vital organ or even system which can be compared with the lung in this respect.

There are at least nine other great organs or systems which are of practically equal weight and vital importance with the lung, among which the remaining mortality is to be divided after deducting quite a con-

[1] Read before the Association of Anatomists, Congress of Physicians and Surgeons, Washington, May 5, 1897.

siderable per cent. for general diseases, accidents, etc., which are not to be classed as belonging to or focalizing in any particular organ or system. Diseases of the entire alimentary canal, for instance, which might justly be divided into three separate regions of the extent and importance of the lung, even including typhoid and cholera, are responsible for barely ten per cent. of the mortality in the human species. Indeed I really ought to apologize for attempting to defend or support the extraordinary morbility of the lung before such an audience as this.

Now, let us look for a moment at the reasons which have been advanced for this high grade of vulnerability. First of all it is usually urged that the lung is peculiarly exposed, especially in the changeable climate of the temperate zone, and more readily attacked by changes in the temperature, moisture, and electric tension of the air which must be breathed into it. But we think this exposure theory begins to reveal its weakness, when we discover first of all that the proportion of fatal lung disease in any given race or class, particularly of tuberculosis and pneumonia, is in exactly inverse ratio to the amount of exposure to all sorts of climatic vicissitudes to which its members are subjected. Diseases of the lung are emphatically diseases of city dwellers, or of such classes in the rural population, as, for instance, farmers' wives and daughters, who suffer from too little fresh air and sunlight. In cattle the same thing is even more strikingly illustrated. Tuberculosis in particular, and pleuro-pneumonia in a less degree, are emphatically diseases of stabled cattle or cattle of limited range, and except in the virulently infectious forms of the latter are comparatively unknown in range cattle. Besides, when we come to look at the wonderfully elaborate and effective mechanisms in the nostril sieve and turbinated steam coils which nature has made for both warming and moistening the inspired air, so that, as was shown by Mackenzie, air at even little above the temperature of zero is raised to within two or three degrees of the body temperature by the time it has penetrated to the nasopharynx, we shall, I think, be able to see on anatomical grounds both the weakness of this exposure theory and the reason why, in its purely mechanical form, it is becoming so universally discredited in clinical etiology. The chilling effect of inspired air upon either nose, trachea, or bronchi is the very least of the factors which result in the production of that most common but positively ludicrously misnamed pathologic process, a "cold," which would much better be termed, if it were not for possible confusion with the language of the diamond, a "foul"—though even this confusion is not so much to be dreaded, inasmuch as both not infrequently result in the verdict, "and out."

But, says the supporter of this view, this may be true as regards mere climatic exposure to perfectly pure air, but the case would be altogether different with the air which very many of these city dwellers are compelled to breathe, loaded as it is with emanations from the bodies and lungs of others, dust, sewer gas, and impurities of all sorts and descriptions. This of course may be granted, and yet we must remember that the wonderfully efficient barring-out mechanism still plays an important part even here, as can be seen by the condition of the nasal mucus after a day spent in a particularly dusty atmosphere, and further that this same course of reasoning would apply with tenfold effect to the stomach under these circumstances. And when we remember the dietetic errors of excess upon the one hand and of deficiency and poverty upon the other, the nauseous slops and messes, the greasy and half-putrefying dishes, sauerkraut, limburger, soda biscuit, "high" game, unleavened bread, and gastric atrocities of all sorts and descriptions, to say nothing of unfiltered water, stale beer, and sour milk, I think we will have to admit that, on *a-priori* grounds, we would expect at least as much fatal rebellion on the part of the stomach as of the lungs. Air in the vilest den is never quite so bad as the food.

The next explanation advanced is that of complexity of structure; that we have here an organ of very high grade, as it were, of vital metabolism, and consequently, like all delicate machinery, peculiarly liable to get out of order; but a single glance, I think, will destroy this theory. Important as the function is, the actual process which takes place in the lung itself is one of the simplest and most purely mechanical that can be found anywhere in the body. All that the epithelium has to do, so to speak, is to keep out of the way of the wild rush of the imprisoned carbon dioxid toward freedom and of the oxygen toward the hæmoglobin. Its sole function is to keep itself alive and keep its pores open.

Then we have the statement made that the lung is almost the only organ in the body which never rests and is obliged to remain in constant activity as long as life lasts. But this is, we think, even more inadequate, for the reason that upon this principle the heart ought to have at least as high a morbility as the lung, instead of having about one-tenth of it; and secondly, that the real active work of respiration is done entirely by the muscles and nerves of the chest, which are extremely seldom the site of disease. The lung proper is as passive in this respiratory movement as it is in the exchange of gases through its epithelium.

These are the explanations usually advanced, and I think you will agree with me that no one of them alone, or all taken together, are in any real sense satisfactory explanations of the extraordinarily high degree of morbility of the viscus. As in other problems, when existing conditions do not appear to explain any given phenomenon we are inclined to turn toward the light of history. And here at once I think we come upon a distinctive and unvarying characteristic of the lung, as an organ, which marks it off from almost all other organs of the body as abruptly and as positively as does its marked liability to the attack of disease, and that is its extreme recentness. With the exception of the uterus and mammary glands, there is no organ in the body which has not from five to ten times the length of ancestral history that the lung has. Appearing as it does for the first time, and in a morphological sense *de novo*, at the level of the amphibia, with no invertebrate history whatever, and but the merest fragments of history in the longest and largest portion of our vertebrate family tree, it is a thing of yesterday, morphologically considered, as compared with any other of the great organs of the body. The stomach, for instance, goes back to the hydria, or even in an impromptu form to the amœba itself. The brain has a pretty respectable representation from the time of the middle cœlenterates and certainly of the worms. The heart goes back to almost the same point. The kidneys have ancestors, of which they might well be proud, in that illustrious predecessor of ours which has been degraded to the base use of concealing fishhooks. The liver itself bears a striking family likeness to its ancestor in Molluscan times; and so on all through the list of our body organs. In short, the lung represents an adjustment of the body mechanism to an extremely late and recent factor in our environment—the direct breathing of air. Can this fact of recentness be said to have any pathologic bearing? We think that it can, and are going to venture to formulate a law upon this subject for your discussion, of which this particular case will be both an illustration and a support, and that is that in pathology as well as in biology the ancestrally old is the individually stable and resisting, and conversely the ancestrally recent is

the individually unstable and vulnerable. But I think some one will say at once: "Have not all our organs also been compelled to adjust themselves to this air-breathing state of affairs? We are land animals, and our entire structure has been modified to meet that change." To which I will venture the reply that not only is this not true in equal degree of other organs, but, strictly speaking, no other organ or organs in the body have so adjusted themselves except in the most superficial manner. We talk about our body republic being an air-breathing and land-living organism, but as a matter of fact all of our citizen cells outside of the lung are still absolutely and necessarily aquatic in their habits, and marine at that; cannot live except when kept continually bathed in a normal saline solution. First of all, upon *a-priori* grounds, I think we should be justified in the conclusion that the longer a given organ has performed its function in an adequate and satisfactory manner (and this is of course simply what is meant by the remoteness of its appearance in the family tree) the more likely it will be to continue to perform that function, undisturbed by any influences which may be brought to bear upon it. The mere presence and history of such an organ, for instance, as the stomach, are a standing "certificate of good behavior" for the past fifteen or sixteen millions of years, and like all other such "characters" would be entitled to considerable weight in calculating its probable performances in the present and the future. And, secondly, I think it will be quite possible to show that those organs or functions which are the last acquired are the first to fail or disappear, either in the normal history of the body or under the stress of adverse circumstances. Take for instance the only other organs of importance which are more recent than the lung itself—the mammary gland and the uterus. Late in their appearance, not only ancestrally but also individually, as to the establishment of their functions, they are the first organs of the entire body to fail and atrophy; in fact, almost the only ones which normally do so before the appearance of actual senility of the general system. And what is their pathological record? One of the blackest for the length of their existence and their importance to the individual which is to be found in the entire mechanism. Nearly eighty per cent. of carcinoma in the female will be found to have its site in these organs, while, judging from the number and clamorousness of our gynæcological brethren, one would almost be inclined to think that the normal state of the average uterus is one of disease, and it would, I think, be a conservative estimate to say that one-third of all women are, more or less chronically, sufferers from some form of womb trouble, even while admitting that much of this may be reflex or but a cloak for our ignorance.

Another case in point is that of the higher cerebral powers, the imagination, the creative faculty, the memory. Appearing for the first time in the higher mammals and at a comparatively late period in the individual, they are among the first to fall before the onslaught of either the febrile or intestinal toxæmias or the general decadence of old age. The same may be said of our power of locomotion in the erect position. Appearing elsewhere only in our double first cousins, the gorilla and ourang-outang, and most difficult of acquisition, in our own anthropoid stage it is one of the first things to disappear under the disabling touch of serious illness or in the development of the tottering and trembling gait of threescore years and ten. The attitude of the white-haired grandsire, tottering along in the autumn sunshine, would be almost absurdly anthropoid, if it were not so pathetic in its helplessness; and the cane with which his feeble balancing power is reinforced is a civilized imitation of the broken bough with the aid of which the gorilla stalks through his native forests.

It need hardly be mentioned that in the realm of morals and manners this law is already accepted as a truism, which has been proved time and again by, for instance, the awful excess of mobs, as during the French revolution, and the frightful disregard for the rights and welfare of others, to say nothing of the decencies and amenities of civilization, which will be shown under the pressure of panic, hunger, or pestilence. The whole of the later veneer of civilization scales off like the viper's skin at the slightest touch of stress or danger, and this rapid blunting of all the social graces and matters of minor conscience, which are the last things acquired in the development of the individual, is one of the most constant and striking symptoms of the approach of chronic forms of insanity. Last to bloom and first to fade is as true of the faculties and even of organs as it is of flowers. If we could speak of the body republic as composed of a confederation of sister states, we would say that the lung was the literal Mexican republic of the entire system—a thing of yesterday by contrast with the stomach or brain, imperfectly adjusted to its new conditions, varying constantly, as I shall attempt to show later, and liable at any time to the outbreak of fatal rebellion or serious insurrection. In short, I believe that nothing less fundamental than some such factor as this will explain the extraordinarily disproportionate morbility and mortality of the lung. Correlated with the recentness of the appearance of the organ is the fact to which we have already briefly alluded, that it is the farthest departure from the original water-loving and water-living type of the primitive cell. There are no other cells in the body which really live in or upon air, even though only upon one of their lateral aspects. All the superficial epithelium of the skin-sheet, so long as it retains its vitality, retains its moisture, and by the time it becomes dry it is practically dead and only mechanically adherent to the body, ready to be shed at any moment. It is perfectly at liberty to protect itself through either oil or keratin, while the lung cell must remain readily permeable.

In short, I believe that we have a fair morphologic basis for regarding the lung as a point of least resistance in the entire organism, a weak spot in the line of defence against the pestilence that walketh in darkness, and this I think will be seen more clearly from the pathologic standpoint, when we come to examine the nature of the majority of the diseases to which it is subject. Head and shoulders above all other processes in these organs stands the "great white plague of the North," as the lamented Holmes vividly termed it—tuberculosis. Tremendous as have been the developments of this disease and wide as the differences of opinion may be as to the balance of its two factors in its etiology, the soil and the seed, all observers are agreed that its most powerful predisposing factor is the lowered resistance in the individual or organ attacked. Of all the deaths which are ascribed to diseases of the lungs in the mortality reports, pulmonary tuberculosis claims from sixty to seventy-five per cent. Nor, I believe, can this extraordinary liability on the part of the lung be accounted for solely or even chiefly upon the grounds of entry or exposure, for the tubercle bacillus is one of the most ubiquitous organisms which has yet been demonstrated in the human tissues. It is to my mind a significant fact that everywhere that it succeeds in effecting a lodgement and establishing a breeding-station is the point at which there are tissue elements of a low degree of resistance, either from rapid growth and the presence of immature cells or from the opposite process of atrophy and absorption. Its commonest sites are the lymph nodes, where the

blood is in process of manufacture; the growth lines of the bones, where a rapid and tumultuous production is constantly going on; the bodies of the vertebræ and intervertebral discs, where the notochord is even yet in process of absorption, and the points where the notochord longest persists are the regions of the vertebral column where tuberculous caries is most likely to occur. I cannot but regard the singular fatality of the pulmonary form of this disease as due not so much to the respiratory tract being the most common proof entry for the bacilli or their spores, but to the fact that here and here alone they find a thoroughly congenial soil in a vital part. Once let the tubercle bacillus get the organism by the lungs, and he can pull it down with as much certainty as the staghound his prey when he once gets it by the throat. Next upon the rôle of infamy comes the dread disease pneumonia, with nearly twenty per cent. of the entire lung mortality to its credit. A few years ago we should have found no support for, but in fact a contradiction of, our theory in the heavy death rate of this process, when it was regarded as an inflammatory and, in the old terminology, a typical "sthenic" disease. Now, however, we simply regard it as due to a lodgement and penetration into a vital organ of a germ which appears not infrequently present in the normal saliva; and its extraordinary preference for the lungs is probably again due to their character as a point of least resistance. Thus we have from eighty to ninety per cent. of the entire lung fatality due to two great diseases, whose chief determining factor is a lowered vital resistance.

Now let us look for a moment at the question of the favorite site or sites of disease in the lung. Is there any one part or region of the lung which clinical experience has shown to be more vulnerable or more frequently the starting-point of disease than any other? For the purposes of this inquiry I shall confine myself to the most frequent and important of the morbid processes—tuberculosis—partly because the changes in this have been more carefully and accurately studied, and largely also on account of the much more gradual and localized development of its symptoms. Pneumonia is as hard to localize as a prairie fire. In this case it is scarcely necessary to ask the question at the head of this paragraph. One of the commonest fundamental pathologic facts in our knowledge of tuberculosis is its extraordinary fondness for the apex of the lung. The proportions vary somewhat among different observers, but all declare that from fifty to eighty per cent. of all cases of pulmonary tuberculosis begin in the apex, and even the second-year student would instantly concentrate his attention chiefly upon this part of the lung in examining the case in which there was any suspicion of this disease. And the consensus of opinion also agrees that of the two apices the right is the more frequently affected in the proporton of about three to two. From time immemorial most elaborate explanations have been advanced to account for this striking and, at first sight, singular preference. I say singular because the apex is, in the first place, the smallest and most definitely limited region of the whole lung substance, and presents not a twentieth part of the area for infection which is offered by the base; and secondly, because if the disease has any connection whatever with irritant or infectious materials, introduced in the inspired air, it is the last place in the world where we would expect, upon *a-priori* grounds, that a lodgement or "settling" of these materials would be likely to take place. Even the bacilli and their spores are known to be ponderable and subject to the law of gravity, and would certainly tend to collect in greatest numbers and with the greatest facility at the lowest instead of the highest part of the organ. The same of course is true as regards the course of congestion or stagnation of either the blood or lymph systems, although it has been gravely declared that certain peculiarities in the arrangement of the pulmonary veins are such as to prevent a proper drainage of this area of the lung and cause it to be a point of deficient circulation and consequently special pathologic liability. And this in the face of the fact that all hypostatic, congestive, or purely inflammatory processes which are known to pathology invariably begin at the posterior aspect of the base. Another explanation which is offered is that in the apex we have a literal cul-de-sac, a point of "no way out here," for both blood and air. The statement must be admitted as perfectly correct. But is it any more true of this region than it would be of any part of the margin of the lung, whether anterior, posterior, or inferior? It is true it is a constricted and cone-shaped projection, but it is not one-half so compressed or "knife-edged" as any portion of the thin leaf-like inferior border, or the irregularly jagged anterior border, particularly on the left side. And it has the advantage of the whole influence of gravity in favor of the return of the blood, instead of against it, as in these other localities. Last, and most weighty of all, we have the theory advanced that the apex is a point of least perfect expansion, and the air-cells, in consequence being less perfectly extended, are more liable to collapse or become filled with catarrhal or serous effusion. As to this purely mechanical version of the expansion theory, I think that only a moment's inspection is necessary to show not merely its inadequacy, but even its absurdity. The cells of the lung are filled not by muscular force or circulatory energy, but simply by the pressure of the atmosphere; and while, if we were dealing with a fluid which had to be forced under pressure into every part of the cavity, we might naturally expect that the highest portion of the cavity would be the one most likely to be imperfectly filled, yet when we remember that we are dealing with a gas, and a heated one at that, the probabilities are absolutely the reverse. Heated air, like any other gas, tends to seek and accumulate in not the lowest, but the highest point of its chamber, and, as far as the mechanical distention is concerned, the cells in the upper part of the lung in the neighborhood of the apex would be more abundantly supplied with air than those in the middle or lower parts of the organ; and this is actually found to be supported by histologic investigation, which has shown that the air cells in the apex are larger and better developed than those in any other part of the lung. The other version, however, of this expansion theory is both rational and weighty, and that is, owing both to the constricted form of the chest at this point, the firmness and solidity of its bony walls, the absence of cartilage and limited movement of the first rib, and the pressure of the shoulder girdles and its great muscles, the normal respiratory rhythm in this region is decidedly limited, and especially is this the case in sedentary occupations or in some forms of manual labor, such as digging, chopping, ploughing, etc., which tend to drag the shoulders forward. This has been developed by Clough into the so-called "postural" theory of the disease. The normal expansive movements being imperfectly performed results in a lowering of the general nutrition and the production of a sort of functional anæmia, which of course predisposes toward almost any kind of morbid process. I would scarcely dispute that, in many cases at least, the stagnation in distention which this theory supposes does actually exist, and is an important factor in the localization of the disease, and yet I am inclined to doubt whether the actual state of activity of the apex has not been very much underestimated. It is perfectly true, of course, that the bony framework of this part of the chest is both limited and rigid, as compared with the

lower regions. But when we remember that we are dealing, as we have already seen, with a heated gas and not with a fluid, and that the whole elastic resiliency and weight of the entire chest wall will, at each expiration, expend itself not only upon driving the air out of the trachea, but also to some degree up into the apices; and further, that while this portion of the chest has firm lateral boundaries, it has no definite roof, and that the pleural cavity actually extends from three-fourths of an inch to one and one-half inches above the border of the first rib, we shall, I think, be justified in questioning whether the immobility of this part of the lung has not been unduly insisted upon. It is of course difficult to get actual observations upon this point, for the reason that after post-mortem rigidity has set in the elastic and continual changing roof of the pleural dome becomes as rigid and unyielding as its bony walls, and even artificial respiration is but a poor substitute in such instances as this for the natural process. I happen, however, to have seen personally two operations in the surgical clinic for the removal of huge masses of (tuberculous) cervical glands, in the process of which the upper aspect of the pleural sac was freely exposed, and the way in which it plunged up and down in response to the respiratory rhythm was little short of appalling, and seriously added to the risks of the operation and the possibility of an accidental puncture by the surgeon's knife. In one case, in a child of about seven, the membrane appeared to have a range in the vertical direction of at least an inch if not an inch and a half, although, seen at the bottom of a gaping wound in the neck half filled with blood, its real range would appear distinctly exaggerated. Be this as it may, I think that I am justified in declaring that neither this theory, nor any other which has heretofore been proposed, is at all adequate to satisfactorily account for the extraordinarily high morbid liability of this region of the lung. When, however, we turn to morphology, we are instantly confronted with the striking and suggestive fact that the apex is precisely the point at which the most active change in the area of the lung is taking place, and hence is again the point of greatest instability and lowered vital resistancee. It is, I think, generally admitted that while the respiratory cavity in mammals is undergoing progressive limitation at both its cephalic and caudal extremities, yet, in man at least, these changes are most active at the cephalic end. This is shown, first, in the not infrequent persistence in adult life, and constant appearance in the embryo, of cervical ribs upon one or both sides; second, in the not infrequent atrophy of the first rib, and, in the internal structure of the lung, in the disappearance of the eparterial system of bronchi. Upon the left side this disappearance is complete, but upon the right side atrophic traces of the system still linger, in the shape of the upper or so-called first lobe, and it is, as we have seen, precisely in this lobe that sixty or seventy per cent. of cases of apical tubercle have their origin. In other words, we have the disease most frequently beginning in that part of the lung which is undergoing the greatest amount of ancestral retrogression, and especially frequent upon that side in which there is still an atrophied remnant of the former development. In fact, I regard tuberculosis as a disease preferring not only the most unstable organ in the body, but the most unstable regions of that organ, and of those regions that side of the median line in which retrogression is still going on. It attacks the weakest side of the weakest part of the weakest organ in the body.

Of course I am aware that the objection will at once be raised that the vestigeal or degenerate nature of this lobe is by no means satisfactorily proved, although the preponderance of investigations and authority appears to point decidedly in that direction. Abey, for instance, from his most careful and elaborate studies of the question, has come most decidedly to the conclusion that the right upper lobe has no remaining counterpart upon the left side, and although Hasse's further investigations have rather supported the view that a process of onward growth headward has been taking place in the human lung, of which the right upper lobe is the first result, yet Weber, LeBouck, and Howes have brought forward considerations which decidedly support the original view of Abey. Unfortunately the ontogeny of man throws but little light upon the question as to whether a symmetrically tri-lobed lung with paired eparterial lobes was the ancestral condition or not, although three cases of a pair of eparterial lobes in man have been reported by Dalla Rosa, and indeed the arrangement of the lungs, as to symmetry, throughout the mammalian kingdom is of the most apparently arbitrary and uncertain character. In a few species, for instance, Bradypus, Equus, Elephas, and Phoca, there is a paired eparterial lobe. But these can hardly be regarded as ancestral or specially primitive forms; nor does there seem to be any possible relation between the phylogeny or the environment of the various forms which will account for either their symmetry or lack of it. In Hystrix, for instance, both the eparterial lobes and their bronchi disappear completely. Nor does our premammalian ancestry throw any further light upon the problem, except that in their very earliest appearance, in Dipnoi, the dividing of the lungs begins at the posterior extremity, the anterior extremities remaining united, and hence the anterior lobes might be regarded as the newest part of the lung. Almost the moment that we land among the amphibia, the symmetry which is originally present begins to disappear, sometimes in favor of the one lung and sometimes of the other, though in the great majority of cases we find the interesting and possibly suggestive condition that the left lung is the one which begins to atrophy, and in the snakes totally disappears. It would of course be a very far cry to say that this ancestral preponderance of the right lung had any bearing upon the marked mammalian tendency for the supernumerary lobe to be retained upon the right side, which of course is the condition in the vast majority of cases. The great name of Wiedersheim must also be added to the support of the "vestigeal" theory of the right cephalic lobe, and the impression is strong from a general view of the entire field that a bilateral symmetry was the original condition of affairs, and that where that symmetry was disturbed the strong tendency is for this to occur at the expense of the left lung. However, as I have said, this is still a disputed question, and Hasse and one or two other investigators of highest standing in Germany are decidedly of the opinion that it represents a new growth, and I have been informed by Dr. Huntington in private conversation that his own studies in this direction have led him rather to this view of the case. However, for the purposes of this discussion, it makes but little difference which view is accepted, all that my postulate requires being that the region should be in a condition of marked instability, which of course would be true in either case. I stated just a moment ago that there appeared to be no connection whatever between the life and habits of any of the mammals in the development of this part of the lung, and so far as balance between the two apices is concerned this is true, but not as to the proportion between this part of the lung and the base in some of the species. Although there are many exceptions, it may, I think, be laid down as a general rule, and indeed I have the high authority of Dr. Huntington for the statement, that the proportional development of the cephalic end of the lung is, if we might use the expression, in excess of the normal in the ungulates, and

particularly in the bovidæ and cervidæ, while, generally speaking, it is below the average in the carnivora. The suggestion has made itself to my mind that probably this condition may be due in the graminivora to the constant pressure exerted upon the base of the lung by the enormously distended paunch, which pressure is so great that in certain forms of gastritis (rumenitis), and also of colitis in cattle and horses, respiration will be so seriously interfered with as to produce fatal asphyxia and rupture of the diaphragm may even result. Be this as it may, we are justified, I think, in stating that the posterior or caudal extremity of the lung in ungulates is to be regarded as the point of the greatest tendency to recession. And here again we have what is to my mind a most interesting and suggestive coincidence, and that is that in domestic cattle the point of most frequent attack and the initial pulmonary lesion of tuberculosis is in the dorso-caudal lobe, though not quite in the same preponderance as in the apex of the human lung. However, Friedberger and Frohner declare that between sixty and seventy per cent. of all cases of pulmonary tuberculosis begin upon the dorsal aspect of the caudal lobe. It would be interesting to compare the morbility of the different extremities of the lung in the carnivora or in the horse with his double eparterial lobe, but unfortunately for our purposes both of these are largely immune to tuberculosis. But it certainly seems a singular coincidence, if nothing more, that this typical disease of lowered resistance should attack in its two principal victims the human and bovine families, in just that part of the lung which lies at a disadvantage either ancestrally or mechanically.

There is one other disease of the lung which it really seems we might almost be justified in regarding as ancestral, and that is emphysema. It has always been something of a puzzle to pathologists why, when every other organ in the body, if inflamed, would undergo either actual solidification or atrophic or sclerotic changes, due to fibroid degeneration with shrinking in bulk, the lung, on the other hand, displays an extraordinary tendency, under almost any form of chronic irritation, to pursue exactly the opposite course and become lighter and more expanded. The usually assigned "back pressure" of cough, or the gasping respiration of asthma, is of course absolutely inadequate by itself, but when we remember that any or all of these causes are acting upon a web of tissue which has gradually grown by complex folding and refolding and meshing from a simple smooth-walled, distended, epithelial sac, such as is still found in the frog and mudfish, we can, I think, hardly avoid the belief that the rarefaction and expansion of the lung in emphysema is simply, as is the case with so many other morbid processes, a reversion to an ancestral stage. No other hollow organ in the body tends to become lighter and more expanded under the influence of chronic inflammation, and no other organ has a similar pedigree. I was much interested in talking with a professional friend a few weeks ago to learn that the great Fothergill had advanced an almost similar suggestion, stating that the "barrel-chest" of chronic bronchitis or asthma was a reproduction of the turtle lung with its expanded air-cells and rigid chest wall; and while the suggestion of the last clause appears at first sight a somewhat whimsical one, yet we have grounds for believing, as I hope to show at some future time, that even the fixed and rigid chest wall, not merely of the asthmatic but also of the consumptive, has an ancestral basis.

Tuberculosis in Cold-Blooded Animals.—Professor Dubard, of Dijon, shows that tuberculosis occurs in cold-blooded animals and can be communicated to them experimentally.—*Province Médicale*, May 15, 1897.

THE TREATMENT OF CANCER BY A NEW METHOD, VIZ., THE ELECTRICAL DIFFUSION OF NASCENT OXYCHLORIDES OF MERCURY AND ZINC.

BY G. BETTON MASSEY, M.D.,

PHYSICIAN [illegible] THE DANE CLINIC [illegible] PHYSICIAN TO THE HOWARD HOSPITAL, ETC.

THE cancerous affections, carcinoma and sarcoma, have been successfully treated by electricity at various times in the past. How extensive the bibliography of the subject is was admirably shown in an article in an English magazine, *The Contemporary Review* for March, 1892, compiled by Mrs. Edith Faithfull, who gave as a reason for her interest in the subject that she herself was a sufferer from epithelial cancer and had been under electro-surgical treatment after two failures of the knife to prevent a recurrence. Some months had then elapsed since an apparently successful result.

Granting the undoubted occurrence of cures by this agent in the many isolated cases reported, it is of interest to inquire why the method has not been more generally used, in view of the reported increase of mortality from this affection under the recognized treatment. This reason was most likely of a threefold nature, including an inadequacy of the method in advanced cases, uncertainty of dosage from lack of acquaintance of the operators with means for measuring the current, and the general dependence of the profession of late on cutting operations.

To Steavenson and Inglis-Parsons, of London, is due the revival of the remedy under modern conditions of electrical knowledge, the latter succeeding in curing a number of mild cases by massive doses of the current, flashed and reversed through the growth from needles of platinum inserted into it and attached to both poles.

It was with these encouraging precedents that I began experimenting with carcinoma of the cervix uteri a number of years ago, and later with sarcoma of other portions of the body, and after several preliminary publications I am now in a position to report results which, though few in number and not always successful, are yet of truly momentous importance to the human race. For as a result of these experiments I can confidently announce that a real cure has been found for sarcoma in accessible locations, and a probable cure for carcinoma similarly situated.

The principle of my method is the interstitial diffusion and impregnation of the growth with nascent oxychlorides of lethal metals by electricity in massive doses. The destructive effect of caustics on these neoplasms is well known, but they act only where placed, exactly as the knife does. By my method a relatively infinitesimal portion of the oxychloride of mercury acts lethally on the cancer cells because of its nascent condition, and because it is carried by the current into the very cells themselves. But the most important point is that by the method we may cause the medicinally laden current to seek out and follow the paths of proliferation of the growth, failure to destroy which is the cause of its reappearance after attempts at extirpation with the knife. It is evident that the cancer cell has less resistance to this interstitial attack than normal tissue, for it is found to lose its vitality at some distance from the electrode without causing necrosis of the healthy tissue, though all tissues in the central portion of the mass will succumb to the method.

The metallic substance is diffused by electrolytic cataphoresis—that is, it is produced by the electrolytic

[1] Read before the section on practice of medicine of the American Medical Association at Philadelphia, June 4, 1897.

destruction of a metal placed within the substance of the growth, the atoms of the metal uniting with the oxygen and chlorine and also with the albumin of the tissues, and this compound, together with still nascent atoms of the metal, is conveyed physically into the tissues by what is called cataphoresis, following the lines of least resistance toward the other pole. Considerable diffusion occurs in all directions beneath this active pole, since the lines of current flow spread out in a widely diverging brush-like form; hence for a proper saturation it is necessary to bring the metal in close contact with all portions of the growth, or else employ a strong current to convey an efficient density to the desired point.

This diffusion of a metal from a corrodible electrode occurs only at the positive pole; it is therefore necessary to connect the active electrode to this pole of the battery. Up to the present time my work has been conducted with active electrodes of zinc, heavily coated with mercury, though it has recently occurred to me that gold and mercury would be a better combination. In action this zinc (or gold) becomes smaller by erosion, but the greatest loss of substance occurs in the mercurial coating, which must be renewed before each use of the electrode. The exact constitution of the metallic oxychloride thus formed has not yet been determined, but it is most probably in the main an oxychloride of mercury.

The cardinal point of the method being a complete and quick saturation of the growth and its ramifications, it is essentially monopolar, the position of the negative pole being so arranged that the whole of the possibly diseased area shall be traversed by the current on its way from the positive or active pole to the negative. This is accomplished in two ways, as follows:

If the growth be small the active electrode is placed within it, and the negative, in the shape of a large pad, on some indifferent surface of the body. Under this arrangement the current traverses a large portion of the body, and on account of the diffusion that will occur through healthy parts I have never employed more than five hundred milliamperes in this way. Cocaine anæsthesia, simultaneouly produced by cataphoresis, is sufficient up to one hundred and fifty milliamperes, but the pain developed above this amperage makes general anæsthesia often best. At the lower current strength it is essential that the application be daily or thrice weekly, and kept up until the whole of the morbid area has been either destroyed or changed into normal tissue before the cavity thus made is allowed to heal. Besides small and recent growths, this method is also applicable to inoperable growths of large size, in which the situation of blood-vessels or important organs renders the more massive and immediate destruction unwise.

The second method, in which an operable sarcoma or carcinoma is destroyed at once, is applied as follows: The patient being anæsthetized, a dozen or more lancet-shaped amalgamated zinc or gold electrodes are inserted around the periphery of the growth, just beyond the area of infiltration, each electrode being attached to one of a leash of fine wires that lead to the positive pole of the battery. The negative pole, a disc covered with absorbent cotton saturated with a solution of potassic arsenite, iodide, or some other salt with a lethal electro-negative radicle, is placed in the centre of the growth itself. It will be necessary to make openings in the skin or mucous membrane for the zinc lancets, owing to their brittleness and dulness. Everything being in readiness, a current of about a thousand milliamperes is turned on through a controller and reliable meter from a current source of proper voltage. The growth will blanch and shrink at once, while areas of destruction appear about each blade and probably in the centre. After a duration of from five to fifteen minutes, according to the size of the growth, the current is turned off, the electrodes are removed, and a dry dressing or acetanilid ointment is applied.

Such is a brief outline of the methods and their technical details, but it should be understood that these details are subject to change in adapting the method to individual cases. The underlying principle that constitutes the novelty is that there is a virtue in the electric diffusion of nascent chemicals throughout a malignant growth which, when of sufficient density per area, will cause an interstitial death and ultimate absorption of the malignant cells at a distance from the electrode, without destroying the connective tissue surrounding them, and that this intracellular lethal action is independent of and additional to the ordinary destructive action of a strong current in the immediate neighborhood of the electrodes. With this important fact established, the cure of cancer in certain localities becomes a mere engineering problem in this age of electric power.

I am happy to state that the truth of these propositions has been corroborated by the independently conducted observations of Dr. J. McFadden Gaston, of Atlanta, Ga., who reported the clinical details of a successful case at the recent meeting of the American Surgical Association at Washington.

The discovery of this peculiar action of nascent oxychloride of mercury and zinc was made while the writer was treating a case of inoperable carcinoma of the groin in August, 1893, by means of a carbon electrode used as the positive pole. The rapid disintegration of the carbon-ball instrument under heavy currents suggested the value of cataphoresis, then already in use in endometritis and other benign conditions, and the mercury was first employed to keep the zinc from adhering to the surface of the wound. But there was an improvement noted in the growth at some distance from the electrode by the next day, and this, coupled with the facts that the use of one hundred milliamperes each time required that the mercury be frequently renewed and that the wound became rapidly aseptic, showed that there was some special advantage in the mercury thus apparently diffused. This case, in which the carcinoma was about three inches in diameter and adherent to the great vessels of the thigh, became much better under prolonged employment of the milder method, nearly the whole of the diseased area filling in with healthy granulations and the gentleman regaining the power to walk, but it was unfortunately impossible to eradicate the cancerous infiltration of the femoral artery and vein, and the termination was ultimately fatal.

Case II.—The second case, and the first apparently complete success, was a recurrent sarcoma of the palate which had been partially destroyed by the writer by ordinary electrolysis in 1893. This man, W. H. L——, aged thirty-nine, had been sent to me by Drs. Hemminger and Bixler, of Carlisle, Pa., with a sarcoma of the left palatal arch fully the size of a goose egg, which he had declined to have removed at the University Hospital. Respiration and deglutition were greatly interfered with. Nearly complete destruction by electrolysis with platinum needles gave him comfort for a year, when it was noticed that lumps were re-developing in the scar. He was at this time (in 1894) placed on the mild zinc-amalgam method, which was kept up daily for six weeks, resulting in a disappearance of the growth after some additional treatment. Three years have since elapsed, and late advices report no sign of return.

Case III.—The third case treated by the method was J. B——, a farmer of Salem County, N. J., aged fifty-five, with an immense epithelial cancer of the face, extending from the external angle of the right eye

to the under border of the lower jaw, the functions of the corresponding eye and ear being abolished and the right ramus of the lower jaw destroyed. Before admission to the Howard Hospital the patient was kindly examined by Dr. Duhring. An effort was made to change the character of this immense surface by the milder method described, the current not exceeding one hundred milliamperes, and the treatment was kept up for some months. As no permanent change of sufficient magnitude was produced, he was finally sent home in a slightly improved condition. I have learned since that he died about a year later.

Case IV.—Mrs. ——, aged fifty, was sent to me by Dr. Saylor Brown, formerly of Williamsport, but now a resident of this city, on October 8, 1895, in a condition of profound anæmia and cachexia from a sigmoidal ulceration of twelve years' standing. She suffered from considerable pain in the right groin, and had from twenty to twenty-five black foul-smelling stools a day.

Local treatment was undertaken with a new hollow sigmoidal electrode devised for the case, with an olive-shaped active surface consisting of mercurialized zinc, and so connected with a syringe that its insertion was facilitated by a cushion of albolene dilating the rectum ahead of the electrode bulb. A stricture was encountered about six inches from the anus, which was extremely sensitive. From forty to one hundred milliamperes were employed with mercury cataphoresis. After several applications a piece of tumor tissue came away, about the size of the last joint of the little finger, and was sent to Dr. Alfred Stengel for microscopic examination, who pronounced it carcinoma. A large number of such pieces came away subsequently, and after a prolonged treatment she was sent home considerably improved in weight and general health, and having not more than two or three stools per day.

Case V.—The fifth case, Mrs. H——, aged thirty-six, of Muncie, Ind., came under my care, March 3, 1896, with a recurrent sarcoma of the left pectoral muscles, about three by four inches in superficial extent, and apparently pressing upon the brachial plexus and axillary vein, for the left arm was swollen and the seat of constant pain. Less than two years before, in July, 1894, the left breast had been removed by Dr. Joseph Eastman, of Indianapolis. This case was an excellent one for the stronger method described, which had not yet been developed. An opening was made through the skin, and a zinc-mercury electrode inserted daily with about one hundred milliamperes, under cocaine cataphorically applied. After a number of applications the swelling and pain in the arm disappeared, and later a piece of the sarcomatous tissue came away, about two and one-half by four inches in size. This resembled a piece of sponge filled with cheesy material, and after its removal the wound was in a fair way to heal. Unfortunately acute mania developed at this time, the patient's mental condition having been suspiciously exalted for some time before admission, compelling her husband to take her home, where the acute mental affection speedily terminated fatally.

Case VI.—Mrs. A——, aged fifty-one, of Salem, N. J., came under my care in June, 1896, suffering from general prostration. In searching for the cause I found a suspicious ulceration of the os uteri, the cervix being enlarged, hard, very irregular in outline, badly ulcerated, and exuding considerable discharge with characteristics of carcinoma. Suspecting malignancy, I at once conferred with her husband and suggested the new treatment. He, however, decided to take her elsewhere for counsel. A week later he brought his wife back to me, saying that he had taken her to Prof. Theophilus Parvin, who concurred in suspecting carcinoma and advised curettage, to be followed later by removal of the uterus. Being still dissatisfied, the patient was taken to a homœopathic physician, who after examination pronounced the affection carcinoma, but proposed that she come under his care for electrical treatment. This latter suggestion caused the gentleman to bring his wife back to me, and she was at once placed on mild daily applications of the mercurial cataphoresis, with currents varying from fifty to one hundred milliamperes. This active treatment did not continue quite six weeks, the local conditions improving rapidly, when she was sent home to return for an application three times a month. This was changed later to once a month. The uterus is now normal, the diseased area being completely healed and general health restored. By appointment I took the patient to Dr. Parvin, May 28, 1897, to verify her present condition.

Case VII.—Mrs. P——, aged seventy, is now under treatment at the dispensary of Howard Hospital for carcinoma of the cervix of the scirrhus variety. The cervix had practically disappeared by erosion when the treatment was begun in the fall of 1896, and the patient suffered from frequent hemorrhages, continuous watery discharges, and hypogastric pain. Under mild applications the hemorrhage ceased, the discharge lost its offensive nature and has nearly ceased, together with the pain, and a cachectic condition has been replaced by relative health. It should have been stated that extensive infiltration of the pelvis existed at the outset of treatment, the vagina being but about one inch in depth and surrounded by unyielding walls. This rigidity of the shortened and narrowed vagina continues, but the whole mass can now be slightly moved.

Case VIII.—Mrs. E. M——, aged forty-seven, came under my care at the Howard Hospital in the autumn of 1896, and hers is the only case so far operated upon by the stronger method described in this paper. A tumor existed in the scar tissue and skin at the site of the right breast, the breast having been removed by Dr. J. William White, at the hospital of the University of Pennsylvania, about three years previously, for carcinoma. The tumor was about the size of a half of an orange. The glands of the axilla had not been removed at the operation previously performed, and were normal. An attempt was at first made to arrest the growth by the milder method, but, this appearing too slow, the tumor was operated upon by mercuric cataphoresis with one thousand milliamperes, at the hospital, May 3d last, in the presence of Drs. A. E. Roussel, E. P. Bernardy, and the hospital residents. The tumor at this time had increased considerably since first seen, measuring three and one-half by three and three-fourths inches. An immediate blanching and shrinking of the growth was noticed, with the production of small necroses at the site of each electrode and in the centre. At the end of thirteen minutes the current was turned off, the electrodes were withdrawn, a dry dressing was applied, and the patient put to bed. The necrosed portions separated painlessly in ten days, leaving an apparently healthy granulating surface; but before this time the interesting fact was noted that the tissues between the electrodes, which had been hard, swollen, vascular, and purplish with malignancy, but had not become necrosed, were now level with the surrounding surface, soft, and possessed of a healthy pink color, showing that an influence or substance passed between the electrodes capable of destroying the cancer cells that was unable to devitalize the normal tissues containing them. All evidences of malignancy had disappeared, except at one spot about the size of a marble, which may require additional treatment.

A review of these eight experimental cases will per-

mit a provisional classification about as follows: Two were cured; two apparently cured; two benefited, of which one is hopeful; and two were failures to arrest the disease.[1]

INFLAMMATION OF JOINTS IN GONORRHŒAL PATIENTS.[2]

By EMANUEL J. SENN, M.D.,

INSTRUCTOR IN SURGERY, RUSH MEDICAL COLLEGE, CHICAGO.

In order to be practical, it is best to speak with Koenig of inflammation of joints in gonorrhœal patients. As a matter of convenience and brevity, it is well to speak of gonorrhœal arthritis, because that term implies etiological and pathological specific meaning. It is rather the exception than the rule to find the specific organism in the exudate of the joint. Nevertheless, the pathological conditions, together with the clinical history, point as conclusively to the gonorrhœal origin as heredity and pathological conditions of a tuberculous joint point to its specific bacterial origin; although the bacteriologist often fails to find the bacillus in the joint contents. Notwithstanding that the joint affection known as gonorrhœal rheumatism was recognized for centuries, it did not receive the attention it deserved until the discovery of the gonococcus by Neisser; when its specific nature, like other forms of metastasis of gonorrhœal origin, was demonstrable in enough instances at least to establish a common origin. Petrus Farestus, in 1507, was the first author who wrote extensively on this subject. At the end of the last century the study of gonorrhœal arthritis gained credence through the observations of Hunter and Ricord; latterly of Loraine and Rollet, who did much to make the affection a distinct nosological entity. Montiggia, at the close of the last century, pointed out the connection between gonorrhœa and rheumatism, and proved gonorrhœal rheumatism to be a distinct form of rheumatic disease. Brandes, in 1854, was the first to bring it before the public as it is known to-day. Gonorrhœal arthritis is not a very prevalent disease, occurring in about two per cent. of all cases of gonorrhœa. It is almost impossible to get a correct ratio of the joint complications accompanying gonorrhœa, for the reason that they appear during the later stages of the acute disease, or a gleet; and when a careful clinical history is not elicited during the course of such a complication the disease is not apt to be traced to its proper source. Patients never think of such an association; in fact, the natural tendency is to shield the guilt of gonorrhœa, and lay stress on the symptoms of the joint complications. It is needless to say that in an enormous number of these cases the affection is erroneously diagnosed as tuberculosis, rheumatism, or otherwise, and consequently the percentage of such complications cited in literature is small. Many theories have been advanced to explain the etiology of gonorrhœal joint complications. We must first consider whether the parent disease is general or local. Andry says that it is inconsistent to speak of a gonorrhœa as a local and at the same time as a general disease. It must always or never be a general affection. It must be admitted that ordinary typical gonorrhœa in its evolution presents no general manifestations in the way of fever or general symptoms, and we should emphatically consider it a local disease. It is only under certain conditions that metastases occur. After the discovery of the gonococcus by Neisser in 1879, gonarthritis became more important in the eyes of the pathologist, as the etiological factor opened a pathway which was formerly shrouded in mystery. Bacteriological examinations of joint effusions were made, and, as failure often attended such efforts, other theories were advanced as an explanation of the primal cause. Rosolimas believed that the gonorrhœal poison produced pathologic conditions at a distance through reflex action on the vasomotor nerves. This theory is also supported by Lewin. Senator explains the cause through inflammatory irritation gradually propagated from the urethra to the sacral plexus and spinal cord, where it affects the trophic nerve fibres. Guyon and Janet have the opinion that gonorrhœal metastasis is the result of toxæmia produced by the ptomains of gonococci in the urethra. Shuster claims that the joint affections may be due to syphilis and gonorrhœa combined. Diday, although believing in the specific infectious character of gonorrhœa as the exciting cause, gives due importance to a rheumatic diathesis as a cause of complications of the disease, such as cystitis, orchi-epididymitis, iritis, and arthritis. Thiry and Guyon maintain that there is no direct connection between gonorrhœa and rheumatism, but surmise that the former through the depressing effects on the system favors the development of a diathesis which has up to the time of the disease, that is, the gonorrhœa, been latent. Peter and Bouillard think gonorrhœal arthritis is due to rheumatism, the gonorrhœa simply provoking the rheumatic diathesis. Duboc is of the opinion that when the disease occurs in later life it is due to a gouty predisposition, because it is more often polyarticular on account of the awakening of the gouty diathesis.

Tammasoli and Hutchinson consider gonorrhœal arthritis only articular rheumatism. Garrod thinks it due to an anæmia. Loeb does not attribute the cause to the action of the gonococcus directly, but supposes that the gonorrhœal process in the posterior urethra plays an etiological rôle by acting as an infection atrium for pus microbes into the lymph and blood streams, and then to the locus minoris resistentiæ in the joint. As proof he mentions the observations of Traube, Koenig, and Lewin. Andry is of the same opinion. He injected gonorrhœal pus into the peritoneum and also into the auricular vein of rabbits without positive results. That the joint affections follow gonorrhœa he thinks is beyond question, but claims that they can also follow ordinary catheterization. Fournier regards gonarthritis to be due to injury of the urethra, and calls it urethral rheumatism. Panas offers this explanation for the arthritis which follows catheterization: "There is erosion of the mucous membrane of the urethra, which acts as an infection atrium to the small superficial vessels. Congestion of the kidneys is the result, not by reason of reflex action, but due to the septicæmia, which causes uræmia and secondarily articular affections." Ricord and R. Bergh think that posterior chronic urethritis is a necessary concomitant for gonorrhœal arthritis. Auvergniot assigns the cause to the gonococcus, although there must be a predisposition. Kammerer believes that as in osteo-myelitis, in which a previous injury may produce a point of least resistance for transient pus microbes, so in gonorrhœal arthritis a previous injury may be a prominent factor. Bond believes the joint complications are caused by a phlebitis of the prostatic veins rather than by an inflammation of the lymphatics, for it is common for the lymphatics to be affected in the early stage of the disease and it is not followed by joint complications. Guérin, Loraine, and Lesègne considered gonorrhœa a general disease, and pointed out in support of their theory the fact that it could produce remote complications. They ascribed the local manifesta-

[1] The last patient mentioned was placed under a second cataphoric operation on June 4th before invited guests from the association and the remaining nodule destroyed by a monopolar application of five hundred milliamperes.

[2] Read before the Tri-State Medical Society, St. Louis, Mo., April 6, 1897.

tions of the disease as a period of incubation, and insisted that no remote complications would ensue if the disease could be stopped during this period, or if it did not extend beyond it. That inflammation of joints during an attack of gonorrhœa, irrespective of whether it occurs during the acute stage or at a later period, is caused solely through the invasion of the gonococcus *per se*, is the *fin-de-siècle* opinion of to-day. Great weight was given to this etiological basis by no less an authority than Fournier. Not only did the discovery of the gonococcus throw light on its migratory character, but the possibility of cultivation of the diplococcus was the basis for philosophical deductions and the means of demonstrating cause and effect. The introduction of the Wertheim nutrient medium (blood-serum agar) opened a new field for the study of the pathogenic action of the gonococcus upon the different tissues. Paltauf and Lang were the first to find the gonococcus in joint effusions and to confirm it by cultivation on nutrient media. Columbina from a joint effusion of gonorrhœal arthritis was unable to obtain any pus germs whatever upon ordinary media; but upon human blood-serum agar obtained abundant pure cultures of the gonococcus. Petrone, Kammerer, Sonnenburg, and Smirnoff found the gonococcus in joint contents, while Leistikow, Haslund, Hoffa, Haab, and Bornemann were unable to find it, but cultivated upon the media instead the staphylococcus pyogenes. Kraske, Brieger, and Ehrlich in numerous examinations have failed to find the specific microbe. Haslund examined the joint exudate in four cases of gonorrhœal rheumatism in periods varying from two to seventeen days after the initiation of the symptoms without finding the gonococcus. Pure cultures from cases of gonorrhœal arthritis have been obtained by Höck, Neisser, and Uffreduzzi, the observation of the last named being conclusive, as the cultures were tested with positive results by inoculation into the urethra. Petrone in two cases of gonorrhœal rheumatism found a micrococcus identical with that described by Neisser in the pus discharge of the urethra, in the blood, and also in the effusion of the affected joint. He concludes that gonorrhœal rheumatism is a metastasis of the specific cause, being transmitted through the medium of the blood to the tissue having a disposition for rheumatic affections. Hewes reports two cases of gonorrhœal rheumatism in which the specific bacterial organism was found in the blood. In one case the cultures of the fourth generation were inoculated upon the vaginal mucous membrane of a dog; thirty-six hours later a thin puriform discharge was visible at the vaginal orifice. A bacteriological examination of this discharge revealed the presence of the biscuit-shaped diplococcus both within and without the pus cells. Distinct colonies of the diplococcus were obtained by culture from the discharge. Hall, of New York, demonstrated the presence of gonococci in the knee-joint in the fourth case on record. During the later stages of the disease he was unable to find them. Kammerer concludes that gonococci do not thrive in a joint fluid more than a few days. In one case he found gonococci on the second day, but was unable to find them later. However, the gonococcus was found in the elbow-joint on the twenty-sixth day by Wyscheminski, in the hip-joint on the fourteenth day by Löwenstein, and in the knee-joint on the twenty-second day by Bergmann.

Joint inflammation can appear during any stage of life, but is most prevalent in young adults, as gonorrhœa is more frequent at that time. Duboc in his able thesis comes to the conclusion that gonarthritis appears most often before twenty-four years of age. This form of arthritis has the appearance of being a primary osteo-periostitis of the epiphyseal cartilage, which is in a state of great physiological activity during this period. According to the same authority, it is often found in the wrist-joint, and most frequently in that of the right hand, because it is used the more often.

Gonorrhœal microbes may cause general infection and localize in joints without being germinated in a specific urethritis. Deutschmann, Panas, von Poncet, Galezowski, Lucas, Tundick, Zatvornicke, and Widmark observed cases following blennorrhœa neonatorum. In quite a number of cases the gonococcus was found in the secretions of the conjunctiva, and also in the effusion of the affected joints. Lucas reports two cases following purulent ophthalmia in infants. In one case, that of a boy eighteen days old, affecting both the left wrist and left knee, syphilis was positively excluded. The mother suffered from acute gonorrhœa at the time of birth. There was purulent ophthalmia of both eyes. The other, an infant three months of age, had an arthritis, implicating the left knee-joint. The child had ophthalmia four days after birth, but inasmuch as it concerned only one joint, Lucas thinks that the arthritis might have been due to accidental causes. Haushalter reports a case of gonarthritis in the newborn, the right knee and left wrist being involved. Purulent ophthalmia was also present. The effusion in the knee-joint contained polynuclear leucocytes and gonococci. In the newborn the affection is generally of a mild type, monarticular, and usually involving the knee-joint. There is little general disturbance, and cure takes place usually in about a month. Gonorrhœal complications of joints are not so likely to occur in the female sex as in the male. This coincidence is probably due, according to Foot, to the fact that the vaginal and urethral mucous membrane is thicker and tougher than the lining of the male urethra.

Davies-Colley claims that the disease occurs as often in women as in men. Auvergniot reports 111 cases of gonorrhœal arthritis in women. One joint was affected in 88 instances, in the remaining the disease was polyarticular.

Philpot reports a case affecting the metatarso-cuneiform joint in a girl nine years of age. Hartley reports 4 cases occurring in the female. Of 252 cases collected by W. P. Northrup, 230 were male and 22 female.

While the disease has a predilection for single joints, in many instances it assumes a polyarticular aspect. Julien found the disease polyarticular in 59 instances and monarticular 41 times. Finger found the knee affected 136 times; tibio-tarsal, 59; wrist, 53; fingers, 35; elbow, 25; shoulder, 24; hip, 18; temporo-maxillary, 10; metatarsal, 7; sacro-iliac, 4; sterno-clavicular, 4; chondro-costal, 2; and intervertebral, 2 times. Northrup found the knee affected 91 times; ankle, 57; foot (small joints), 40; wrist, 27; heel and toes, 21; elbow, 18; hip, 16; shoulder, 16; hand (small joints), 11; sterno-clavicular, 3; and temporo-maxillary, 2 times.

Hortelloup reports two cases of gonorrhœal arthritis of the sterno-clavicular joint. Loeb says the knee-joint is most often affected and the wrist-joint very seldom. Davies-Colley declares that the disease can occur in any joint, but he found it most frequently in the elbow-joint. In those predisposed to gonorrhœal arthritis, one attack does not furnish a lease of immunity to subsequent attacks. When the joint lesion is due to a specific urethritis, each catheterization is liable to cause an exacerbation of the joint symptoms or to produce the disease in other joints. Later attacks of gonorrhœa, whether due to an awakening of a latent process or to an additional infection, are followed almost without exception by joint complications. Hermet reports a case, in the

service of Professor Fournier, of a man thirty-five years of age, of apparent good health, who in six years contracted gonorrhœa five different times. Each attack was followed by conjunctivitis and polyarticular arthritis. Basset observed a patient who in one year had gonorrhœa five times, presumably an auto-infection, followed each time by painful arthritis. There was a typical hydrarthrosis of the knee and elbow. The disease also attacked the smaller joints, not the usual seat of rheumatism, such as the temporo-maxillary, sterno-clavicular, metatarso-phalangeal, and the bursæ of the retro- and sub-calcanea. After each catheterization for cystitis and stricture, there were exacerbation of fever and pain in the joints.

The gonococcus does not, as a rule, leave its habitat, the mucous membrane of the urethra or conjunctiva, while it is exerting itself in acute inflammation. It is only when the acute symptoms have subsided that the latent microbe finds its way, through some secondary cause unknown at the present day, into the general circulation or into the lymphatic system, and subsequently by it reaches a serous membrane at a distant seat. Of sixty-five cases of gonorrhœal rheumatism, Brandes in fifty-one found gleet as its precursor, in seven acute gonorrhœa, and in seven it was impossible to tell whether the joint lesions originated in an acute or in a chronic gonorrhœa. The gonococcus on mucous membranes such as the urethra and conjunctiva acts as a pus microbe; but in its migration to serous membranes it plays an inferior rôle, exciting rather a plastic inflammation. Bumstead says that gonorrhœal rheumatism is essentially a hydrarthrosis and suppuration very rarely occurs. Instances of suppurative arthritis have been observed during a gonorrhœa, although such is rarely the case, and then it is in all probability not pus due to the action of gonococci, but is the result of a mixed infection, the same as an infective arthritis following scarlet or typhoid fever. On mucous membranes the gonococcus has the action of a pyogenic microbe; the pus is not the direct result of the gonococcus but of the chemical substances produced by it. This is evident from the very fact that pus corpuscles appear before the specific agents have reached the vascular layer of the membrane. The gonococcus first attacks the surface of mucous membranes and only after passageways have been formed by the inflammatory changes do the deeper structures become implicated. The gonococcus has a special predilection for mucous membrane, as is well shown by the regularity with which purulent ophthalmia is produced by the infection of the conjunctiva with gonorrhœal pus. The real seats of gonorrhœal infection are the mucous membranes lined with columnar epithelium. Andry believes that the gonococcus, when in course of emigration to predisposed joints, maintains its viability in the blood through the oxygen it contains. Again its possibility of thriving on serous membranes speaks in favor of cells of the papillary type for its maintenance. Aubert says the blennorrhagic secretion is alkaline. The gonococcus thrives better on membranes with an alkaline reaction. In the bladder the gonococcus is not so persistent as in the urethra, which is alkaline. It is well known that the life of the gonococcus in joint cavities is short, since effusions of gonorrhœal joints have been examined soon after the symptoms presented themselves, with positive results as regards the specific cause, while subsequent examinations proved negative, although the symptoms pursued the typical cycle after the disappearance of the primary cause. This has been the verdict of some of the most expert and competent pathologists, including Kammerer, and for this reason the specific cause from a metastatic standpoint is still doubted by a small minority of authorities on this subject. Analogically speaking, we need only look to the peritoneum, which is a specialized form of mesoblastic tissue similar to the synovial membrane of joints. Consider, as pointed out by Sinclair, the two different pathologic rôles played by the same microbe on tissues of different embryological origin. The gonococcus, while causing purulent inflammation of the mucous membrane of the Fallopian tubes, in the surrounding connective tissues is not prone to suppuration, but manifests an intrinsic vegetative capacity by the formation of adhesions. We find the same pathological condition in joints. Of two hundred and seventy one cases observed by Bornemann, only three were of a purulent nature. Of eleven cases in which Haslund aspirated gonorrhœal joints, he found the contents in ten of a purulent nature, or on the border line of being pus, the so-called catarrhal pus of Volkmann; but he was not able to find the specific cause. In the other case the contents were hemorrhagic. The patient was constitutionally undermined, and the joint was massaged for a long time. He compares this condition to the analogue of an incipient hemorrhagic exudate in pleurisy, the result of a low constitutional condition. The ten so-called purulent cases were not evidently of pyogenic origin, but simply simulated pus. In the last few years, Koenig has done more than any one else in the investigation of the pathological anatomy of gonorrhœal joints. As he states, the mortality of this disease is so small, and arthrotomy is so seldom called for, and the opportunity for visual inspection of the pathological field is so limited, that at the present time the true pathology is in need of enlightenment.

Koenig gives the following classification:

Gonorrhœal arthritis.

1. Hydrops articularis.
2. Hydrops articularis sero-fibrinosus et catarrhalis (Volkmann).
3. Empyema of joint.
4. Phlegmon of joint.

The simple hydrops is the mildest form and has a tendency to definitive healing. The fluid contents are of a clear synovial type. The fibrinous form is characterized by a hydrops in which there are flocculent masses and which has a great tendency to cause ankylosis. Empyema of a joint in gonorrhœal patients is rare, as verified by statistics. The phlegmonous type is a severe form of inflammation, in which the ravages of the gonococcus are of a very destructive character. There are erosion and disintegration of cartilages, thickening of the capsule and ligaments, and a phlegmon of surrounding connective tissues often accompanied by inflammation of bursæ and tendon sheaths. In the severe forms of joint inflammations, even with little external swelling, great damage can be done. Koenig has seen a marked genu valgum formed and a backward luxation of the tibia in arthritis of only ten or twelve days' standing. The same authority has observed absolute bony ankylosis, in which the entire joint cavity was obliterated without a vestige of its anatomical identity being left, in three months' time. There is no other disease with such a marked tendency to ankylosis, except a form of arthritis following puerperal fever, which also manifests a marked tendency to ankylosis and which probably ultimately is of gonorrhœal origin. Bradford reports a case of ankylosis of the vertebræ following gonorrhœal rheumatism and extending from the seventh cervical vertebra to the sacrum. Fournier mentions a form of gonorrhœal arthritis which has a predilection for the small joints of the foot, causing great deformity. He speaks of the subject under the title "Pied blennorrhagique." Amarel wrote an exhaustive thesis on this form of arthritis. He called

it "Affection polyarthrite deformante progressive pseudo-noueuse." It attacks the phalanges, which are deformed, and there is amyotrophy of muscles. He observed nine cases of this variety in Fournier's clinic, and concludes that it is probably an atrophy of reflex origin. According to Roustan, when there is a gonorrhœal peri-arthritis there is great liability to muscular contractures. Dercum reports the case of a man thirty-six years of age with gonorrhœal arthritis of the right knee and right elbow, followed by inflammation in other joints. Four weeks later there was muscular wasting of the upper and lower extremities. Electrical examination showed no qualitative change in the muscles. At the time of the report the patient was improving. Myrtle reports the case of a man thirty-two years of age—gonorrhœal arthritis of the right knee and wasting of muscles of both sides from the hips downward, showing the origin of the atrophy to be central and not due to the arthritis. Souplet, His, Leyden, Councilman, and Wilms observed cases of gonarthritis complicated by endocarditis and myocarditis.

The clinical history of gonorrhœal patients is variable. There is a complexus of symptoms which are characteristic of the different forms. Gonorrhœal joint complications may be acute or chronic. The rule is that when the precursor is a chronic urethritis the joint invasion is initiated by acute symptoms. It is very seldom indeed that joints are infected during the acute disease. The inflammation may attack one joint alone; but often it may first be multiple. Roustan described cases in which the pain was not localized. About three weeks after the incipiency of the gonorrhœa, there was slight fever with tenderness in the neighborhood of certain joints, but without marked swelling or œdema in the region of a particular joint, and which lasted several hours or days. The same symptoms appeared in other joints, being of a fugitive nature, when finally the disease selected some joint in particular and became monarticular. He is of the opinion that this peculiar localization of the disease needs further observation and investigation. Acute gonorrhœal arthritis usually makes its appearance from four to six weeks after the primary symptoms of the gonorrhœa. The pain is intense. There is elevation of the temperature to 103° F., or even 105° F., and a corresponding acceleration of the pulse, often ushered in by a chill. The pain is worse at night and the slightest movement causes the patient to cry with pain. The whole area around the joint is tender, but there is no particular spot of tenderness. There is flexion of the joint due to the patient assuming the position affording the greatest degree of relief. According to Bond, a pathognomonic sign is tenderness of the heels in walking. The swelling of the knee-joint is peculiar and almost diagnostic, the effusion being most marked in the upper part of the joint under the vasti muscles. After exudation into the joint, digital palpation will reveal fluctuation. When the inflammatory process has become peri-articular, there is great œdema. The muscular structures above and below the joint become atrophied. The discharge from the urethra diminishes or ceases to flow during the height of the joint inflammation, but when the acute symptoms begin to decline it again appears. The acute form can gradually become subacute and then chronic. During the course of a gonorrhœa, the chronic form of arthritis may assert itself, coming on insidiously with slight symptoms. There is a gradual filling of the joint with a catarrhal transudate. These cases present almost identical symptoms with a tuberculous hydrops, except that in the latter there is often a point of tenderness in the epiphyseal line, denoting a primary osseous tuberculosis and a secondary synovitis. In adults the diagnosis is difficult, as the synovial tuberculosis is primary. The clinical history and macroscopical and microscopical examination of the aspirated joint contents will throw light on the diagnosis. Koenig believes that the urethra should be investigated in every case of acute catarrhal inflammation of joints, and that in ninety-nine out of every hundred it will be found to be of gonorrhœal origin, provided there is a blennorrhagic discharge. This positive opinion of such an eminent authority should have great weight, as doubtless hundreds of cases of gonorrhœal hydrops are diagnosticated and treated as tuberculous affections. Hutchinson's contention is that in patients who are gouty or rheumatic, any urethral discharge, specific or not, may give rise to symptoms similar to those of gonorrhœal rheumatism.

The disease with which it is most apt to be confounded is polyarthritis rheumatica. The fever in gonarthritis does not continue long. The disease is more chronic, continuing, according to Nolens, two months or more; while, according to Lebert, in polyarthritis rheumatica the average duration is only forty-one days. Gonorrhœal rheumatism affects one or few joints. If a new joint is attacked, the one previously disturbed does not become free, as is the case in acute rheumatism. The joint affection is between a serous and a suppurative synovitis. Gonorrhœal arthritis is more often complicated with inflammation of tendon sheaths and bursæ than articular rheumatism, while in the latter endocarditis is more often a concomitant.

The prognosis as regards the mortality is favorable. Death is seldom caused by this disease, except when there is an accompanying gonorrhœal endocarditis or meningitis. On the other hand, it is very grave when considered in reference to functional results. According to Koenig, when the joint effusion is of a distinctively catarrhal nature (Volkmann), the prognosis is relatively good. If passive motion is resorted to early enough, the patient may escape even stiffness of the joint, much more ankylosis. The rule is, however, that, in spite of the best medical and surgical care, there is apt to be more or less functional interference. The outlook is more favorable if the ankylosis be of a fibrous nature, but unfortunately it is more often osseous. Auvergniot reports twenty-three cases affecting the wrist; in sixteen there were no bad after-effects, in the rest stiffness and ankylosis. In thirteen cases involving the knee-joint, only four subjects escaped permanent injury.

The treatment rests upon the etiological basis. In the absence of more convincing evidence we must assume a predisposing cause in conjunction with the essential one, the gonococcus. The fact that joint complications appear only in two per cent. of all cases of gonorrhœa bespeaks a predisposition, whether anatomical, rheumatic, or gouty. The fact that salicylic acid and its salts have a favorable action on the disease, although they do not shorten the duration, forces us, I believe, to assume a rheumatic diathesis as a prerequisite at the present time. Alkalies, such as salicylates, salol, carbonate of lithium, and citrate of potassium, are antirheumatic and antiblennorrhagic. The routine medical treatment of these cases in the surgical clinic of Rush Medical College is the iodide of potassium in moderate doses, and the results are invariably good. Jullien claims that the oil of wintergreen comes nearest to being a specific of any of the remedies used. R. W. Taylor reports favorable results from internal administration of this drug in twelve cases. Shuster works on the basis that joint complications may be due to gonorrhœa and syphilis together. Swellings of the tuberosities of the tibia, the sternal joints, or sacrum should call for mercurial treatment. Jullien treated a sixteen-year-old girl, suffering with gonorrhœal rheumatism, with subcutaneous injections

of corrosive sublimate. After nine injections the disease was cured. The fever was combated with antipyrin and salicylates, which remedial agents were in all probability the true cause of the favorable result. The original focus should not be lost sight of. Lucas, in a case of purulent gonorrhœal ophthalmia which was the primary cause of the general dissemination, applied strong lotions to the eyes and diminished the discharge, with a correspondingly improved arthritis, followed later on by a complete cure. Ricord and R. Bergh, believing that posterior urethritis is necessary for gonarthritis, claim to have prevented it by means of abortive injections, thus limiting the urethritis to the anterior portion of the canal. The urethra should receive antiblennorrhagic treatment; especially strictures should call for proper treatment, as an infection atrium is liable to remain posterior to such an obstruction. The joint should be placed at rest on a splint and surrounded by hot fomentations, followed later on by equable pressure by means of adhesive strips. Absorption should be promoted by pressure, external medication, or puncture, as occasion demands, for the tendency of these effusions is to remain and cause ankylosis. Jullien recommends external inunction of ichthyol ointment in the strength of fifty per cent. in lanolin. The French even to-day resort to vesication in para-articular processes. Koenig believes in the external use of tincture of iodine in phlegmonous peri-arthritis. He lays great stress on the proper application, and insists on not simply applying a salve but thorough medication to the point of blistering. In the hydropic form, Koenig taps the joint, injects carbolic acid, and also resorts to vesication and compression. When the hydrops is sero-fibrinous, aspiration and injection are all the more necessary. Fütterer, of Chicago, injected one-half drachm of the oil of sandalwood in the affected joint, with brilliant results. He resorted to this treatment in four cases. During the first forty-eight hours after injection all the symptoms were exaggerated, but a gradual permanent amelioration followed, with no functional disturbance remaining. In case of empyema of the joint, immediate incision and tubular drainage are indicated.

Christen is very radical in the treatment of this disease. He advises arthrotomy in all cases as soon as possible after the onset. If the disease is multiple, two or three joints should be opened daily. He claims immediate cessation of pain, falling of temperature, and no ankylosis. The subsequent treatment consists of immobilization and massage. After the acute symptoms have abated, absolute rest may be maintained by a plaster-of-Paris cast, but this should be of short duration. Vicious position should be guarded against in case of ankylosis. If there is an inclination to erosion of the cartilages or bone in the joint, traction by weight and pulley is of great importance to remove the pressure of contiguous structures. For the realization of the best ultimate hopes, too much stress cannot be laid on the importance of scientific massage and active and passive motion.

A STATISTICAL STUDY IN EPILEPSY.

BY L. PIERCE CLARK, M.D.,

FIRST ASSISTANT PHYSICIAN AT THE CRAIG COLONY FOR EPILEPTICS, SONYEA, N. Y.

In a careful study of ninety-five hundred and forty-five seizures which occurred in one hundred and fifty cases of epilepsy admitted to the Craig Colony during the past year, considerable attention was devoted toward ascertaining whether the attacks occurred in periods; but the results showed that there was no periodic recurrence of seizures which could be at all definitely predicted from time to time. These observations are contrary to the experience of some investigators in epilepsy, who maintain that the malady is as much a regularly periodic disease as it is a convulsive one.

It has been frequently stated by neurologists that the generative functions are in close connection with the higher cerebral centres, and in most mental diseases, as well as in many convulsive ones, the organs of generation are diseased, which disorder is very often regarded as a cause of the nervous disease or figures prominently as a result of it. During the year's study upon the female epileptics at the Craig Colony, it was noticed that, although at the time of their admission many patients (and very frequently their friends) stated that the seizures appeared regularly at the menstrual period, yet this was not borne out by observation of such cases after admission. For several months the convulsions, in a very few cases, appeared three or four days before and after the menstruation began, but when such patients had become thoroughly accustomed to colony life the apparent association disappeared. The greater number of the female patients were remarkably free from genito-urinary disorders.

When we take into account the fact that epilepsy is a disease which often makes its first appearance during the night, and may exist for years as such, we would naturally infer that the greater number of attacks would occur at night; but the records kept at the colony show that the greater number of attacks occur during the day rather than by night, being in the ratio of five to four. This may be accounted for in a measure by the fact that the treatment in the majority of cases was a bromide-chloral one, and chloral, when given at night, is a well-known remedy which throws nocturnal seizures into diurnal attacks. A plausible explanation for this fact rests upon the physiological action of the two drugs. The ultimate effects obtained from bromide and chloral are about the same. The effects of bromide are much longer felt but are less slowly produced when compared with those of chloral. Both drugs probably have their main action upon the circulation. Obviously, for rapid effect, chloral would have the advantage over bromide. As morning approaches, after a night dose of chloral the unstable nervous centres approximate the condition of a fulminant, but receive a check by a relatively weaker drug which proves impotent to prevent the explosion of nervous substance. Consequently a seizure which would have occurred at night is, with chloral treatment, tided over until the morning or the following day.

The hour of the day (twenty-four hours) in which the greatest number of epileptic attacks occur has been differently stated by neurologists. Some have said that they occur with greater frequency in the early morning hours, between eight and ten o'clock. Féré has stated that practically no attacks occur between the hours of eleven and twelve o'clock in the forenoon.[1] In a study of nineteen hundred and eighty-five attacks, he found but three occurring at this hour. That this statement is not in accord with statistics at the Craig Colony may readily be seen by reference to the appended table of the record of nearly ten thousand seizures, which have been tabulated by each hour in the twenty-four during each month from March, 1896, to January 1, 1897—a period of ten months. The time of occurrence of each attack in the twenty-four hours, its duration, and its character are a part of the permanent record of each case at the colony. This table shows that three hundred and seventy-eight attacks occurred between eleven and twelve o'clock, making this hour rank sixteenth in the order of frequency of the whole number for the twenty-four hours. It will be seen that the number of attacks at this hour is only twenty below the average. The greatest number of attacks have been found to occur at the hour of four o'clock in the morning; the least number at seven o'clock at night.

TABLE SHOWING 9,545 EPILEPTIC SEIZURES, ARRANGED TO SHOW THE NUMBER OF ATTACKS WHICH OCCURRED IN EACH HOUR DURING THE DAY FOR A PERIOD OF TEN MONTHS.

1 A.M.	353	13 P.M.	412
2	411	14	443
3	433	15	424
4	537	16	337
5	453	17	341
6	498	18	253
7	392	19	224
8	339	20	344
9	355	21	455
10	420	22	485
11	378	23	394
12 M.	435	24	420
		Total	9545

The diet for epileptics has been so arranged that the heaviest meal of the day occurs at noon, and the progress of stomachic digestion of food is probably complete in two hours. Then we have a decided remission in the frequency of attacks, that continues until the nine o'clock hour, when they once more occur frequently. Nevertheless we should be guarded in accepting this explanation as an adequate one to settle the question, as the antithetical idea has been used to explain the supposed great infrequency of attacks occurring at the eleven-o'clock hour, which we have found to have little or no basis in fact.

Aside from the auto-intoxicant theory for convulsive disorders, which has been and is still being so assiduously urged by Haig and Bouchard, the epileptic is still known to be a person incapable of receiving any sudden excessive or otherwise abnormal impression anywhere throughout the whole organism, and especially in the alimentary tract. This is well exemplified by the fact that nearly one-half of the patients admitted to Craig Colony suffer from more or less severe constipation.

The reception of food and its assimilation are one of the very primitive habits of life, yet any abnormal departure from its regular and methodical processes cannot but act disastrously to the whole organism. The recognition of this fact has led to the present careful consideration of the dietary for epileptics. From a simple methodical principle, any abnormal departure in diet would act as a fulminant to the unstable nervous centres in the epileptic's cerebral cortex.

In drawing any conclusion in regard to the cause for seizures appearing more frequently at one time than at another, we should consider the metabolism of the whole organism and its influence reflexly upon the nervous system. This undoubtedly is the first and greatest factor which should be studied in order to solve the question of the frequency of attacks at certain hours during the day. As for the greatest number of attacks occurring at 4 A.M., two reasons may be

[1] Dana's "Text-Book of Nervous Diseases," chapter on Epilepsy.

given to explain the great frequency of the phenomenon. It is one of the sleeping hours when the epilepsy is farthest away from the sedative action of the chloral and bromide, as the patient generally awakens some time during the eight-o'clock hour. Again, the night spent in sleep is well known to be a time when reflex activity runs riot in the organism. All the vital forces are at their lowest ebb at 4 A.M., and, above all, the nervous system is especially defenceless and open to the reception of reflex action.

There are undoubtedly many other factors operative in certain cases of epilepsy besides reflex and digestive disturbances. While we are aware that such a study as is here presented in this article is not at all conclusive and final, yet we do believe that such a tabulation of statistics has a certain value and interest. We hope in time to see such studies, by means of such untiring investigation as has characterized scientific research in other more tangible diseases, contribute their share toward solving the mystery of the causation of epilepsy.

Clinical Department.

PROLONGED PREGNANCY AND PREMATURE OSSIFICATION OF THE CRANIUM, CAUSING DYSTOCIA.

By H. S. BAKETEL, M.D.,

DERRY, N. H.

Early in March I was engaged to confine Mrs. E——, multipara, aged twenty-seven. She expected her accouchement March 27th. I heard nothing from her until the morning of April 26th, when I was called in by the husband and given the subsequent facts. She had her last menstrual flow June 20, 1896. Shortly after its cessation she went away on a visit and was absent from her husband nearly two months. Her pregnancy had been uneventful. About March 25th she had pains, and, thinking the labor near at hand, sent for her nurse. These pains continued several days and stopped suddenly, leaving her very lame in the right leg. The fœtus at once became more active, but there had been no further signs of labor. The woman had given birth to three children. The first, born September 8, 1890, came at full term and lived twelve days. The second, born February 1, 1894, died shortly after birth; this confinement was twenty-five days later than expected. The third confinement came November 24, 1895, after a difficult labor, lasting seventy-eight hours; it was twenty-eight days late.

On examination I found the os undilated and labor evidently some time away.

About eleven o'clock on the night of April 28th I was summoned, and found the os dilated three fingers and made out a left occipito-anterior presentation. The pains, occurring about once in ten minutes, lasted on an average seventy seconds. The head had not engaged. One hour later examination showed no change, except that the os had fully dilated, and in two hours the conditions were the same.

Shortly after this the pains decreased in severity, duration, and frequency, and on April 29th did not occur more than once in twenty minutes. That night they assumed their former character, but repeated examinations showed no progress.

Pains continued intermittently April 30th and May 1st. Late in the night of the latter day I called in consultation Dr. David S. Clark and Dr. Frederick Perkins. It was decided to wait until daylight, and then remove the child with axis-traction forceps or do a craniotomy, as the circumstances warranted. I gave hypodermatically one-half grain of morphine sulphate and one-one-hundredth grain of atropine sulphate, and ordered repetition in two hours if the pains did not desist. Notwithstanding these precautions, there had been steady pain, and at eight o'clock the next morning when we saw the patient the head had engaged, but seemed wedged in position.

Under chloroform anæsthesia the low forceps operation was done, and the woman delivered of a male child weighing eleven pounds ten ounces. The delivery was so difficult that it was feared craniotomy would have to be resorted to, but perseverance rendered this step unnecessary. The child was large and finely developed, with diameters about three-fourths of an inch above the average. There was complete closure of the occipito-parietal fontanelle, while the fronto-parietal was exceedingly small. The sutures were very firm and could not be felt. The occipito-mental diameter was six and one eighth inches, the biparietal four and one-fourth inches, the fronto-mental four and one-eighth inches, and the suboccipito-bregmatic four and seven-eighths inches.

This woman, who is unusually strong, was in hard labor from Wednesday morning until Sunday morning, or ninety-four hours. She ran over the allotted two hundred and eighty days a period of thirty-six days, making her pregnancy continue three hundred and sixteen days. I am fully convinced of the truth of the mother's statement as to the last menstrual function and absence of intercourse. The large size of the child and his strength both in muscle and voice show advanced development.

It has been judicially decided in the United States that a pregnancy may last three hundred and seventeen days. Thompson[1] reports a case in which pregnancy lasted three hundred and seventeen days from the last menstruation, and three hundred and one days from the last coition. In the *Boston Medical and Surgical Journal*, May, 1859, a pregnancy of three hundred and thirty days was noted. Dr. A. L. Rodenstein[2] reported four cases, in which pregnancy was prolonged on an average two months. Maur[3] had a pregnancy continuing three hundred and thirty-four days. Olshausen[4] is of the opinion that the duration of pregnancy should not be restricted to three hundred days, but that the limit be extended to three hundred and twenty-five. Spiegelberg[5] and Winckel also believe that pregnancies can be prolonged far over two hundred and eighty days.

Legally the authorities of this country differ. In the case of United States *vs.* Collins,[6] tried in the United States District Court for the District of Columbia, in which the defendant was on trial for non-support of a bastard child, the presiding justice ruled that a living child could be born after a gestation of between six and twelve months; and the Supreme Court of Indiana, in the case of The State *vs.* Dill [7] for bastardy, allowed that pregnancy could continue three hundred and thirteen days.

Medical literature comments on the rarity of ossification of the cranium and prolonged pregnancies; hence this report.

BILATERAL CONGENITAL AMAZIA.

BY FRED. C. ZAPFEL, M.D.,

CHICAGO.

By referring to the literature on this subject I find that this is a rather rare occurrence, and one which, according to some authors, is found in monstrosities only. It has been my good fortune to have seen a case of this kind, and I take this opportunity of putting it on record.

Some time ago I was called to see a lady, who had been suddenly attacked by a violent pain over the heart, followed by unconsciousness. Upon examination I found a complete absence of both breasts. The chest was well formed, but there were no mammæ. It was not a case of micromazia, as I at first suspected, but a total absence. The nipples, however, were large, like a normal female nipple, and had a pigmented areola around them.

The lady is thirty-two years of age, married eight years, has had five miscarriages, all at about the sixth month, and has given birth to five children, two of which are twins. The labors were all normal. She has menstruated only once since her first pregnancy, and is now again four months pregnant. She gives a history of having never been sick, and claims that her breasts were at no time larger than they are now. She has an aortic insufficiency now. The history shows that this is not a case of atrophy, either primary or secondary, but of true bilateral congenital amazia, without a concomitant infantile uterus.

331 CLEVELAND AVENUE.

HYDRAULIC DILATATION OF THE URETHRA.

BY J. F. RUMER, M.D.,

DAVISON, MICH.

THE following is a short description of my method of treating retention of urine caused by any condition that produces a lessening of the calibre of the urethra short of absolute and complete closure. I have been advising this long enough to become perfectly satisfied that it is absolutely harmless, and if properly practised by an intelligent patient is of inestimable value. Instead of dilating with sounds or using a catheter, I have for the past two years instructed my patient that once every day, when getting ready to pass water, he should press the index finger firmly against the meatus so as completely to prevent the urine from escaping, and slowly and carefully exert pressure by contracting the muscular coats of the bladder. Thus is obtained a degree of water pressure that is considerable, and at the same time is equally distributed along the urethra, in such a manner that all irritation, such as cannot but be produced on the surface of that delicate lining membrane with a sound or catheter, no matter how skilfully used, is avoided. Pressure is made, and thus dilatation is effected in a safe, pleasant, and efficient manner. I firmly believe that there is also a general toning up of the muscular parts that are concerned in the act of micturition, and possibly of the seminal parts of the penis, as I have frequently had men impotent tell me that after practising this method a while they seemed to be regaining their lost functions. I believe it strengthens the muscular coats of the bladder, gives more power to the expulsive effort, increases the size of the stream, and makes the act of micturition in this class a natural physiological function instead of a pathological experience. Every physician can call to mind patients who day and night every two or three hours must go to the closet, take a catheter, and draw a few drops of urine, and scarce recover from the discomfort of the act before it must be repeated.

I am firmly convinced that, if this method of treating these cases is faithfully followed, very much suffering can be avoided.

SPINAL HYPERÆMIA WITH VICARIOUS MENSTRUATION.

BY FREDERICK D. TYRRELL, M.D.,

SPRINGFIELD, MASS.

TEN weeks ago I was called in to attend Miss J——, a strong, healthy, plethoric girl, seventeen years of age, for "paralysis." It had been her habit to flow five or six days each month, and during her last period, the night being warm, she placed her feet through an open window and fell asleep. Toward morning it grew very chilly, and when she awakened she found that her menses had ceased. She complained of a "fire in her backbone," pins and needles in the feet, and finally complete paraplegia with anæsthesia, as shown by pricking the limbs with needles and applying heat and cold. I made a diagnosis of spinal congestion caused by the suppression of the menstrual discharge, and resorted to the usual treatment of leeches, ergot, and quinine, with gratifying results.

During my absence she complained to her mother that her feet felt cold, so a hot flatiron was applied. In some manner the iron worked its way up as far as the calf of the leg, and caused an ulcer there the size of a silver dollar, which I dressed daily.

In the course of a week her menstrual flow appeared and continued for five days. Meanwhile, the sore on her leg bled profusely and ceased only when the menses had stopped. I paid no attention to this and continued to dress it regularly.

The next month when her menses again appeared, the heretofore comparatively dry wound again began to bleed, and, as before, continued throughout the period of menstruation.

The patient is now up and able to be about, and the wound is entirely healed.

ICHTHYOL IN A CASE OF CHRONIC PURULENT INFLAMMATION OF THE MIDDLE EAR.

BY THERON W. KILMER, M.D.,

NEW YORK.

THE case in question was that of a boy, six years old, who had complained of frequent attacks of intense pain and a continuous discharge from his right ear, dating from an attack of scarlet fever seven months previous. Upon examination I found a moderate amount of thick pus and crusts lining the auditory canal, which having been cleansed, the drum exhibited the following appearance: it was of a pale color, with a slight perforation in the posterior-inferior quadrant. Hearing was to some extent impaired. After thorough cleansing of the parts with warm water, a pledget of cotton was soaked with a three-per-cent. solution of ichthyol, and placed close up against the eardrum. A second piece of cotton was loosely placed over this as a means of protection. After two days the patient again visited my office, and the cotton was removed. All pain had ceased, the discharge was less, and the parts appeared better in every way. The ear was again packed as before, and with a third subsequent treatment the discharge was totally stopped, there has been no pain, and the hearing is a very little improved.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, July 31, 1897.

GONORRHŒAL ENDOCARDITIS.

FOR a long time it was supposed that rheumatism was the principal cause of endocarditis, with its consecutive valvular defects, but evidence has been gradually accumulating that these complications may attend any infectious process, and possibly also any toxic process, under suitable conditions. In the case of the infections it may be assumed that, as a rule, an active, acute inflammatory process is set up as a result of the lodgment of infective principles (bacteria) upon and within the endocardium; while in that of the intoxications the process is rather a slow, chronic, hyperplastic, or degenerative one. It is to be borne in mind that under the former conditions a state of intoxication is often also developed, so that at times both sets of etiological factors are operative in the same case. The infectious endocarditis is most likely to be of the verrucose, ulcerative, or malignant variety; the toxic of sclerotic or indurative type.

That gonorrhœa, among other infections, is capable of causing endocarditis, as well as other serious complications, has come to be recognized only within comparatively recent years. Attention had been called prior to 1870 by French observers, and some ten years later by the Germans, to the occasional clinical association of the two disorders. MacDonnell, of Montreal, in 1891 insisted upon their etiological relation, and Leyden, before the Berlin Society for Internal Medicine in 1893, seems to have been the first to demonstrate the actual dependence of the endocardial lesion upon the activity of the gonococcus, which Neisser in 1889 had shown to be the cause of the urethritis. The infectiveness of the gonococcus has further been shown by its capability of inducing, beside urethritis, cystitis, epididymitis, orchitis, etc., also synovitis, arthritis, abscess, myelitis, and inflammation of serous membranes.

A considerable, withal not large, number of cases of gonorrhœal endocarditis has been reported since Leyden's communication upon the subject. In the majority, although the gonococcus could be found on microscopical examination, culture experiments proved unsuccessful, owing to the sensitiveness of the microorganism to external influences. An additional case of this kind was reported by Siegheim (*Deutsche medicinische Wochenschrift*, May 13, 1897), at a recent meeting of the Berlin Society for Internal Medicine.

The patient was a woman who came under observation on account of chills, followed by fever, occurring daily for two weeks between twelve and half-past twelve noon. Examination disclosed a faint systolic murmur over the tricuspid orifice, with a pulse frequency of 112, but no elevation of temperature. The appearance of the patient, however, aroused a suspicion of ulcerative endocarditis, and this was strengthened when it was learned from the husband that he was suffering from an attack of gonorrhœa. In the further progress of the case a systolic murmur became audible over the mitral, and later a loud diastolic murmur over the aortic orifice. The pulse increased in frequency, became dicrotic, irregular, and intermittent, and finally distressing palpitation and great dyspnœa set in. The fever pursued for a time a typical intermittent course, subsequently becoming irregular. The spleen became gradually enlarged and appreciable on palpation. Vomiting set in, and finally blood and albumin appeared in the urine, the secretion of which further became notably diminished. Dyspnœa and cough became aggravated, until death resulted amid symptoms of pulmonary œdema.

Post-mortem examination disclosed the existence of proliferative ulcerous endocarditis of the aortic valve, with myocarditis, pulmonary œdema, nephritis, parenchymatous hepatitis, endometritis, and purulent cystitis. During life inoculations of agar-agar and peptone-bouillon were made with blood obtained by puncture of a vein, but with negative results. Smear preparations likewise failed to disclose the presence of micro-organisms. Inoculations with blood obtained from the heart at the autopsy also yielded negative results, but in smear preparations and in sections made from the endocardial vegetations and examined under the microscope diplococci were found possessing all the characteristics of gonococci.

The failure of bacterial colonies to develop in the inoculated culture media in this case is considered sufficient to exclude the presence of the ordinary pyogenic cocci. The gonococcus, on the other hand, has been shown to be extremely sensitive to thermal variations, developing only within a certain narrow range of temperature. As the autopsy was made in this case twelve hours after death, the negative results of the inoculation-experiments need not therefore be viewed with surprise; nor can they be considered as throwing doubt upon the identity of the organisms observed under the microscope.

"THE IMMORALITY OF THE ANTIVIVISECTION MOVEMENT."

THE above is the title of a striking article in *The Open Court*, written by Dr. Paul Carus. In it the antivivisection movement is stripped of its sentimentalism and the subject is presented in a common-sense and practical manner. The antivivisection party have always posed as the exponents of the teaching of the Christian religion, and have insisted that Christianity and vivisection are incompatible. They hold that vivisection is immoral. This has been at all times their strongest argument. Dr. Paul Carus denounces

this proposition, and presents the case in a quite different light. He contends that the immorality rests with the antivivisectionists, and says: "The antivivisection movement, as it is carried on, is in a sense guilty of immorality, and we deem it our duty to state our views of the subject openly and frankly. The two greatest religious leaders of mankind, Buddha and Christ, have taught us to have compassion, but neither the one nor the other prescribed to avoid once and for all the infliction of any suffering. On the contrary, they taught that suffering is unavoidable. Buddha did not say that salvation is obtained by yielding unreservedly to the sentiment of compassion; he taught salvation by enlightenment. And Christ's mission is mainly a lesson of sacrifice, which means that salvation is obtained through suffering."

And again he says: "As to vivisection, we all know that it is not a pleasant duty of the physiologist, but it is an indispensable task that must be done for the sake of investigation. It falls within the same category with all sacrifices. Vivisection may truly have, and frequently will have, the tendency of blunting the sentiments of the vivisector; but so does dissection. Shall we surrender dissection as an obligatory part of medical instruction, lest the moral sense of the student be shocked?" The article concludes with these words: "Vivisection, if strictly kept within the limits of its important purpose, is a moral obligation; and he who would hinder the physiologist in the performance of his duties makes himself guilty of immoral conduct; but any cruelty to animals — viz., every lack of respect for life, every thoughtless or wilful infliction of pain, every delight taken in torturing, injuring, or destroying sentient beings — is a crime that should be denounced and reprimanded, and, if necessary, checked by the power of law."

THE ETIOLOGY OF MULTIPLE SCLEROSIS.

Although many of the etiological factors of this interesting disease have been determined in recent years, the true cause of the affection has not yet been established, and according to some studies of Blumreich and Jacoby it would appear that a variety of etiological moments may be invoked. The account of these investigations, based upon a clinical study of twenty-nine cases observed in Gerhardt's clinic at the University of Berlin, is published in the *Deutsche medicinische Wochenschrift* of July 8, 1897. Of the twenty-nine cases studied, twenty-three occurred in males, six in females. Twenty-two were between the ages of twenty and forty, and seven between forty and sixty. In some the first symptoms were noticed early in life. A number of the patients had suffered from infectious diseases during childhood; but in only one of all of the cases was there any direct relation between the infection and the nervous disorder. This case occurred in a man of twenty-five, in whom the symptoms of multiple sclerosis developed in the sequence of an attack of influenza. In only one of the cases could a history of syphilis be elicited with certainty; in three a doubtful history of this kind was obtained. In six of the cases there existed the possibility of intoxication as an etiological factor. Two patients were addicted to alcoholic excess, but in both instances other causative influences might have been operative. One patient had suffered from carbon-monoxide poisoning nine years before the advent of his nervous symptoms. Three patients had been exposed to industrial intoxications. Two of these were painters, who had, however, never exhibited other symptoms of plumbism. In one there had been chronic suppurative disease of the ear from childhood, together with eye changes suggestive of multiple sclerosis prior to exposure to lead. In the other the first symptoms of nervous disorder followed immediately upon traumatism. One patient was occupied in exhausting glass bulbs employed for incandescent electric lighting, and had suffered from mercurial intoxication. In nine cases the patients attributed their trouble to grief and overexertion, but in five of these there existed the possibility of other etiological influences. In all of the cases special inquiry was directed to the influence of traumatism in causing the nervous affection; and in eleven cases positive evidence of this nature was secured. In the remaining five the presence of other etiological possibilities and the length of time between the two events caused doubt as to the relation between the injury and the disease of the brain and cord.

This study shows that there is no constant, universal cause for multiple sclerosis. In some cases the mode of origin escapes recognition. In others there are three main groups of exciting causes, viz., acute infectious diseases, intoxications, and traumatism. These may operate by the direct action of the injurious agencies in inducing the anatomic changes in the nervous system; by rendering apparent previously latent disease; and by acting as predisposing influences that favor the action of the exciting causes. It is possible that traumatism may not really play any part in the etiology, being perhaps in many instances an accident due to the vertigo and unsteadiness symptomatic of the already existing neruous disorder.

COMPARATIVE EFFECTS OF DIFFERENT ALCOHOLIC DRINKS ON MAN.

The investigations of Lancereaux concerning the changes taking place in the nervous system from the abuse of various alcoholic drinks are of much interest. The following are some of his conclusions regarding the effects of spirits, wine, beer, and absinthe: "In excessive use of alcoholic drinks of high percentage of alcohol, the tactile and thermal sensibilities do not seem to be greatly altered, while sensibility to pain seems exaggerated. In those who use absinthe and similar drinks to excess, the plantar reflexes are increased, light tickling causing movement, while slight stroking of the knees, legs, or abdomen causes pain severe enough to make the patient complain. Similar results, though less marked, are to be observed in the upper extremities. In wine drinkers this sensitiveness of the skin is much less in the lower extremities, above

there may be a zone of hyperæsthesia, while still higher normal skin sensation is the rule. Psychical symptoms in absinthe drinkers are stated to be fewer than is generally supposed, and, as is taught in the ordinary text-books, wine and alcohol drinkers are prone to attacks of acute delirium, while in those who drink alcoholic essences forms of dementia are more liable to follow."

News of the Week.

The Floating Hospital of St. John's Guild was struck by lightning on Friday last, and a baby was killed in its mother's arms. The same shock caused the premature birth of another child.

Obituary Notes. — Dr. Charles O. Baker, a prominent surgeon of Auburn, N. Y., died at his residence, July 16th, from cerebral hemorrhage. He was born near Auburn in 1852, and was graduated from the medical department of the Syracuse University in the class of 1873, practised general medicine in and about Auburn until 1890-91, when he visited Europe, taking a special course of operative surgery under Lawson Tait. After that he devoted himself almost exclusively to abdominal surgery. — Dr. William Thurman died at his home in this city last week, at the age of fifty-six years. He was a graduate of the College of Physicians and Surgeons in this city in 1864, and served later on the house staff of the New York Hospital. He was an active member of St. John's Guild, and had always been especially interested in the work of the floating hospital. He was also a school physician, having been appointed by the mayor about a year ago.—Dr. Louis F. Kiefer died in this city on July 23d, at the age of forty-five years. He was a graduate of the College of Physicians and Surgeons in 1886, and then served as interne in Roosevelt Hospital. He was prominent in masonic circles. —Dr. Delos A. Crane died at his home in Holland Patent, N. Y., on July 22d, at the age of seventy-six years. He was a graduate of Castleton (Vt.) Medical College in 1844.—Dr. William H. McNaughton, of Watervliet, N. Y., died on July 22d, at the age of thirty-four years, from pulmonary tuberculosis.

A Prize for the Discovery of the Bacillus of Yellow Fever.—It is announced that a bill has been introduced into the Brazilian legislature, offering a prize of $220,000, in two equal parts—one to the author of a work demonstrating the existence of the bacillus of yellow fever and the surest and readiest means of its recognition; and the other to the discoverer of an effective treatment of the disease. The decision upon the award shall be made by the Medical Institute of Rio Janeiro, the Hygienic Institute of Berlin, and the Pasteur Institute of Paris. A further provision of the bill authorizes the reservation of a sum of $110,000 for the founding of an establishment for the preparation of a curative serum, the discoverer of the same to be the organizing director of the institute. The first of these prizes will doubtless be awarded to Dr. Sanarelli, whose paper announcing the discovery was published in the Medical Record of last week, and it is most probable that the second will also fall to him. Such substantial rewards for medical discoveries are only too rare.

Reports of the State Board of Charities. — The State board of charities' report on the deaf has lately been issued, and from a perusal of it the facts are gathered that in the various schools in the State there are a total of 1,467 pupils, 817 of whom are males and 650 females. On the whole, these children seem to be well cared for both in mind and body, but the inspectors wish to call the attention of the managers of each institution to the differences in the tables containing the standing of their schools. According to the report of the committee on Craig Colony, it is in a satisfactory condition, and has, since its opening in January, 1896, made marked progress. In the case of the epileptics, open-air employment has been found to be very beneficial. Commissioner Bergen reports on Kings County Hospital in very unfavorable terms. He states that the overcrowding is excessive, the accommodation for nurses is defective, and the lighting is bad. He characterizes the institution as improperly equipped and ill constructed. Commissioner Marvin reports on the various institutions in the third judicial district, and says that he finds that those institutions under the management of sisterhoods and the hospitals in charge of trained nurses are more successful than those otherwise controlled. The report of the State commissioner on the poorhouses in the eighth judicial district is in most respects favorable. There were at the time the report was made 1,151 inmates in the eight poorhouses in the district. The commissioner passes severe strictures on the management of the Erie County poorhouse, but the seven other ones appear to be in a good condition. The report of the committee on the institutions in this State for idiots and feeble-minded states that all these establishments are under the best care and management. Many structural improvements are needed, however, at the State asylum in Rome, the dining-rooms in the basement being in a very unsanitary and uncomfortable condition.

The Chautauqua County Medical Society.—The annual meeting of this society was held at Chautauqua, N. Y., July 13, 1897, under the presidency of Dr. E. S. Rich. The annual election of officers resulted as follows: *President*, Dr. Morris N. Bemus, Jamestown, N. Y.; *Vice-President*, Dr. V. M. Griswold, Fredonia, N. Y.; *Secretary and Treasurer*, Dr. Charles A. Ellis, Sherman, N. Y.; *Censors*, Drs. T. D. Strong, Westfield, N. Y.; W. M. Bemus, Jamestown, N. Y.; J. Murphy, Sherman, N. Y. The president's address was "Notes on Puerperal Eclampsia." A large number of cases was reported. Dr. W. W. Hotchkiss, of Jamestown, N. Y., read a paper on "Tonsillitis." Dr. T. D. Strong, of Westfield, read one upon "Influenza." Dr. Lucien Howe, of Buffalo, presented a case of "Diphtheritic Membrane of the Eyelid," which had existed many months. At 8 P.M. Dr. R. R. Ross, superintendent of the Buffalo General Hospital, lectured upon

the *x*-rays, illustrating with the apparatus as he proceeded, taking a photograph of a fractured femur at the close.

The Hamburg Hospital.—Dr. H. Kümmell, surgical director of the New General Hospital (Neues Allgemeines Krankenhaus) of Hamburg, in the name of the local Hamburg committee and also in that of the general imperial committees of the Twelfth International Congress, invites those going through Hamburg on the way to Moscow to inspect the hospital, and particularly the new hygienic establishments in that city. The medical men will be at the hospital daily, from 10 A.M. to 2 P.M. Still they request that American visitors will kindly notify them, if possible, of the day of their visit.

Appendicitis and the Berry Crop.—The seed theory of appendicitis has become so widespread among the laity that it is said to have interfered very seriously with the sale of small fruits this season. The result is that the unsuperstitious and the "appendicized" are enjoying an abundance of the healthful berries, to the scandal of their timid neighbors.

The Independent Medical College, of Chicago, would appear to be an institution needing investigation by the postal authorities. It is advertising in the daily papers to make lawful physicians of those who pursue a "home course" of study.

The Prince of Wales' Hospital Fund. — The largest contributor to this fund was Mr. W. W. Astor, who has promised to give $5,000 annually, the next largest annual contribution being $1,250.

The Russian Red Cross Society, in return for the action of the New York society, has established two beds, one at St. Petersburg and the other at Odessa, for the care and comfort of patients from the United States navy.

A Grave Charge against a Surgeon.—The charge has been made that two Hindoo girls were assaulted at the Khana plague inspection camp by European officials. A surgeon, police sergeant, and a hospital attendant have been suspended for their alleged participation in the assaults, and the governor of Bengal has ordered an inquiry to be made concerning the charge.

A Monument to the Hunters.—At a recent meeting called in Glasgow, a committee was appointed to collect subscriptions for a monument to William and John Hunter. It is hoped to raise about $20,000 for this object.

Mortality among Foundlings in Italy. — The Roman correspondent of *The Lancet* called attention a short time ago to a foundling asylum in Naples, in which in the course of two years among eight hundred and fifty-six patients admitted only three had survived. Among other causes for this incredible mortality was the nursing of three or four infants by one wetnurse. An only less ghastly exhibit is made by the foundling hospitals of Venetia, the area of which is twenty-four thousand square kilometres, and the population nearly three million inhabitants, and which sends annually to the foundling hospitals a mean of one hundred and forty thousand infants, the vast majority of which are illegitimate. Among this number the mortality is fifty-two per cent., as a result primarily of want of nourishment, and secondly of neglect of every description. The administration of the several hospitals costs annually some $3,000,000, derived from the bequests of benefactors and the contributions of the provinces and communes.

Mississippi Valley Medical Association.—At the next meeting at Louisville, October 5, 6, 7, 8, 1897, the address on surgery will be delivered by Dr. J. B. Murphy, of Chicago, and that on medicine by Dr. John V. Shoemaker, of Philadelphia. Title of papers should be sent to Dr. H. W. Loeb, secretary, St. Louis, Mo.

The Italian Society of Internal Medicine will hold its eighth congress at Naples in October next, under the presidency of Dr. Guido Baccelli. In connection with the congress there will be an exhibition of hydrology and climatology, and of instruments and appliances used in medical practice.

Prosperous Ophthalmic Surgeons.—*The Lancet's* special commissioner on hospital abuse says that the leading ophthalmic consultants in London daily have to send away patients who pay the highest fees, simply because there is no time to see them all. This is probably the reason why the Queen sent to Germany for an oculist to examine her eyes, the London men being doubtless too busy to attend to her. The same writer says that no one in London will operate on a poor man for cataract for a fee of $50, unless he is moved thereto solely by a feeling of charity.

Grandmotherly Legislation in the United States.—An anticigarette bill has passed the lower house of the Tennessee legislature by a unanimous vote, and it is expected that it will also pass the senate. The bill prohibits absolutely the sale of cigarettes and of cigarette papers in the State. The law is to come into effect on May 1, 1897. If it be true that every people has the government which it deserves, the good folk of Tennessee would appear to be of those of whom it was said, "Blessed are the meek."—*British Medical Journal.*

A Monument to Duchenne of Boulogne.—On Sunday, June 27th, a monument was unveiled in the square of the General Infirmary of the Salpêtrière to the memory of the celebrated Duchenne, who was born at Boulogne in the year 1806, and is universally known by the title of Duchenne of Boulogne. M. Barthou, the minister of the interior, presided at the ceremony, and Professor Joffroy, physician to the Asylum of St. Anne and president of the memorial committee, pronounced a eulogium on Duchenne. He recalled the two great names of Trousseau and Charcot—of Trousseau, who made generally known the work of Duchenne with regard to locomotor ataxia; and of Charcot, who was, he said, the great worker in the science

of modern neuro-pathology and one who had rendered the greatest possible service to the study of affections of the nervous system. On the pedestal of the monument is the following simple inscription: "1806–1875. To Duchenne of Boulogne. Localized electrization; Physiology of movement; Neuro-pathology." Professor Raymond, physician to the Salpêtrière, charged himself in his official capacity with the duty of demonstrating in their midst the innumerable labors of Duchenne. Dr. Lerboullet, of the Academy of Medicine, read a paper by Professor Mathias-Duval upon the works of Duchenne, and after an address by Dr. Motet, of the Academy of Medicine, who spoke in the name of the Medical Society of Paris, M. Barthou concluded the series of speeches. In the most brilliant fashion the minister of the interior tendered his respectful homage "to the marvellous unity and modesty of the great savant to whom they that day, perhaps somewhat tardily, were giving his well-deserved tribute of glory." A point to which the minister did not refer at this official ceremony, at which the faculty and a host of medical officeholders were present, was that Duchenne never at any time was either a professor or a hospital physician. He worked all alone, going round the wards every morning examining and questioning the sick himself, and was looked upon as a madman by all the officials. Only by the worth of his works, and that at a long time after his death, has he attained his right position, for during his life he met with nothing but scorn from the official scientific world.—*The Lancet.*

International Conference on Railway and Steamship Hygiene.—The second international congress of "les services sanitaires et l'hygiène des chemins de fer et de la navigation" will be held in Brussels, on September 6, 7, and 8, 1897. Those desiring to take part in the congress are requested to send name and titles, with address and five francs, to Monsieur le Docteur J. de Lantsheere, Rue de l'Association, 56 Bruxelles, Belgium.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending July 24, 1897. July 20th.—Passed Assistant Surgeon L. W. Spratling detached from naval hospital, Norfolk, and ordered to naval hospital, Philadelphia, July 19th; Passed Assistant Surgeon R. M. Kennedy detached from naval hospital, Philadelphia, July 19th, and ordered to naval hospital, Norfolk; Assistant Surgeon J. C. Pryor detached from naval laboratory, New York, and ordered to the naval hospital, Mare Island, Cal.; Assistant Surgeon W. M. Wheeler detached from naval hospital, Mare Island, and ordered to the *Oregon;* Assistant Surgeon A. Farenholt detached from the *Oregon,* ordered to Washington with insane patient, then to the *Vermont;* Assistant Surgeon C. E. Riggs detached from the *Vermont* and ordered to the New York navyyard. July 22d.—Medical Inspector A. F. Price detached from the New York navyyard, July 14th, and ordered to the *Olympia* as fleet surgeon; Medical Inspector J. A. Hawke ordered to the New York navyyard, August 14th; Medical Inspector J. G. Ayers detached from the *Olympia* as fleet surgeon, ordered home, and granted two months' leave. July 23d.—Surgeon H. E. Ames detached from the *Cincinnati,* July 25th, and ordered to the naval hospital, Yokohama, per steamer August 14th; Surgeon J. C. Byrnes detached from the Norfolk navyyard and ordered to the *Cincinnati,* July 25th; Surgeon P. Fitzsimons detached from naval hospital, Yokohama, on relief, ordered home, and placed on waiting orders.

Dr. Donald McLean, of San Francisco, dean of the California Medical College, was shot on Friday last by a discharged employee of the college, and was dangerously wounded. His assailant killed himself when about to be apprehended by the police.

Don Juan Creuz y Manso, of Madrid, one of the most progressive and best known of Spanish surgeons, has recently died. He was the translator of the greater part of the Spanish edition of Ashhurst's "Encyclopedia of Surgery." He was the first surgeon in Spain to advocate and practise antiseptic surgery, and was also the first in that country to perform a successful ovariotomy.

Disease in India.—Reports from Bombay state that there has been an alarming increase in the number of deaths from cholera in the presidency since the middle of July, and that there has also been a slight increase in the number of cases of the plague, which had been regarded as practically extinct. The natives of India seem to be awakening to the need of greater efforts to eradicate the endemic diseases of the country, and the viceroy has announced that native chiefs of India have undertaken to found an institution for the scientific investigation of Indian diseases in commemoration of the jubilee.

Bellevue Hospital Medical College.—Dr. E. G. Janeway has been elected president of the faculty of Bellevue College, to fill the vacancy occasioned by the death of Dr. William T. Lusk.

Foreign Medical Practitioners in Italy.—Dr. Santini, a member of the Italian chamber of deputies, the author of the attempt to drive all foreign physicians out of Italy, occupies his time chiefly in inquiring of the government how soon the foreigners are to be forced to give up attending to their sick compatriots. The last time he interpellated the government, early this month, the representative of the latter replied that medical practitioners of non-Italian nationality would be allowed to practise among Italians in Italy if Italian medical men had the same privilege conceded them by the other nationalities in question. The sanitary laws, still in force, allow foreign medical men to practise among their compatriots resident in Italy if they do not extend their *clientèle* to Italians. The abuse of this privilege will be carefully guarded against in the future, as it has been in the past, but the Italian government is probably too wise to risk driving away many rich and money-spending tourists in an attempt to throw a few patients in the way of Dr. Santini and his fellow-practitioners.

Reviews and Notices.

NEURAL TERMS, INTERNATIONAL AND NATIONAL. By BURT G. WILDER, M.D., Professor of Neurology, etc., in Cornell University. Reprinted from the *Journal of Comparative Neurology*, VI., December, 1896.

ALTHOUGH by no means prepared to accept *in toto* the principles of Dr. Wilder's nomenclature or its application, nevertheless we heartily recommend this opuscle to our readers, neurologists and general practitioners alike. The careful painstaking labor, the comprehensive knowledge of his subject, we may even say the manly fashion in which the author receives the contumely and attempt at ridicule of those whose position in the scientific world makes such conduct particularly unfitting—all command our admiration. That Dr. Wilder is continually receiving converts to his mode of nomenclature is shown by the fact that Van Gehuchten, in the recent edition of his work on the anatomy of the nervous system, adopts it in many important respects.

DISEASES OF THE EYE AND OPHTHALMOSCOPY. A Handbook for Physicians and Students. By DR. A. EUGEN FICK, University of Zurich. Translated by ALBERT B. HALE, A.B., M.D., one of the Ophthalmic Surgeons to the United Hebrew Charities; Consulting Ophthalmic Surgeon to Charity Hospital, Chicago, etc. With a Glossary and 158 Illustrations, many of which are printed in colors. Philadelphia: P. Blakiston, Son & Co. 1896.

THIS work forms a volume of four hundred and eighty-eight pages, is of convenient size, well printed, beautifully and quite fully illustrated. The author may be congratulated on having secured such an admirable translation of his work; all the points of the original are retained and are expressed in excellent English, free from the Germanisms so frequently met with in translations from that language. The plane of the work is high, and it will be read most understandingly by students and practitioners who have already obtained some knowledge of physiological optics and clinical ophthalmology.

The part devoted to the discussion of external diseases is undoubtedly the weakest in a very strong whole. Omission of the discussion of some of the rarer diseases, as molluscum and actinomycosis, and failure to mention the pneumococcus as a cause of one form of acute conjunctivitis, are noted. One is surprised to find the following: "There is no doubt that infection with the gonococcus of Neisser and with the diphtheria bacillus of Klebs-Loeffler can produce a conjunctival diphtheria." The omission to mention the method of "expression" in the surgical treatment of trachoma, the suggestion to use hot compresses of camomile tea in the treatment of corneal ulcer, and the statement that keratitis striata is probably due to wrinkles in the cornea, do not comport with a work supposed to be up to date.

Honest criticism of the work would compel the statement that there is little that is new in its pages; indeed some of the text bears marks of antiquity, as the description of the pathology of retinitis albuminurica; however, these are minor faults and few. The work as a whole is well written and evidences a wide knowledge of ophthalmology on the part of the author and of the translator. The parts relating to physiological optics are excellent.

A NEW CLASSIFICATION OF THE MOTOR ANOMALIES OF THE EYE, BASED UPON PHYSIOLOGICAL PRINCIPLES, TOGETHER WITH THEIR SYMPTOMS, DIAGNOSIS, AND TREATMENT. The Prize Essay of the Alumni Association of the College of Physicians and Surgeons, New York, for 1896. By ALEXANDER DUANE, M.D., Assistant Surgeon, Ophthalmic and Aural Institute, New York. New York: J. H. Vail & Co. 1897.

THE care in preparation, exactness in statement, and beauty of expression which have always characterized the writings of this author are not wanting in this brochure of one hundred pages. The careful study of the action of the extrinsic muscles of the eye, extending over a long period of time, is presented in a carefully digested, impartial statement of the conditions met with, given in the light of a full knowledge of the work of others in physiological optics and in the normal and abnormal dynamics of the eye. A complete analysis of the movements of the eye, as produced by the individual and combined action of the eye muscles, is given, and this is followed by a very ingenious diagram illustrating these movements in a graphic manner. The discussion is sufficiently comprehensive to present a clear exposition of the subject; it is direct and free from verbosity. The laws given for the determination of feeble and paretic muscles, the discussion of the anomalies of individual muscles and the statements regarding contractures subsequent to insufficiences of opposing muscles, paretic or otherwise, are all excellent.

Although the classification advocated is somewhat cumbersome, it is based on facts, and the terms employed are accurate and clearly descriptive of the conditions to which they are applied. There is little to criticise and much to commend in this work. It should be read by all who are interested in the subject of the anomalies of the muscles of the eye.

INJURIES AND DISEASES OF THE EAR. Being reprints of papers on Otology. By MACLEOD YEARSLEY, F.R.C.S., Fellow of the British Laryngological, Rhinological, and Otological Association; Surgeon in Charge of the Department for Diseases of the Throat, Nose, and Ear, The Farrington Dispensary, etc. London: The Rebman Publishing Company, Limited, 1897.

AS stated in the preface, the papers have appeared before in various journals and have been collected together to form this little volume. There are six papers, making a volume of forty pages. The work is of value to the general practitioner, as it contains many precepts relating to the most common pathological conditions met with, in a readily accessible form. To the aurist there is little of interest except the last article, which treats of aural reflexes. There are no illustrations.

RETINOSCOPY (Or Shadow Test). In the Determination of Refraction at One Metre Distance, with the Plane Mirror. By JAMES THORINGTON, M.D., Adjunct Professor of Diseases of the Eye in the Philadelphia Polyclinic and College for Graduates in Medicine. Twenty-four Illustrations. Philadelphia: P. Blakiston, Son & Co. 1897.

THIS little volume of sixty-three pages is intended for the use of undergraduates in medicine and for those taking postgraduate studies. It is an extremely elementary exposition of retinoscopy, good so far as it goes, with the exception, perhaps, of some theories regarding the oblique position of the lens in certain cases, which are irrelevant and possibly not correct. A practical knowledge of retinoscopy may be gained by the perusal of the work. The pages are well illustrated.

CLINICAL LECTURES ON MENTAL DISEASES. By THOMAS S. CLOUSTON, M.D., F.R.C.P.E., Lecturer on Mental Diseases in the University of Edinburgh. Fourth Edition, Thoroughly Revised.

CLOUSTON'S treatise on mental diseases, although not the most scientific of British treatises on insanity, is unquestionably the most satisfactory to students and to physicians, and in every instance a safe, reliable guide in the handling of the diseases to which it is devoted. One rises from reading a chapter or a section with the fullest conviction that he has been listening to a man experienced in the practice, learned in the theory, and versed in the literature of his subject. The more the volume is studied the more convinced does the reader become of this fact. The book has its serious faults, from the viewpoint of the American psychiatrist, but some of these it shares with all other Anglican text-books on the same subject. The subject of paranoia is discussed in two pages. This, of course, is a decided gain, in what we venture to believe is the right direction, over complete ignoring of the subject, the rule in text-books on insanity by British "medical men." Nevertheless, it may be truthfully said the handling of the subject in the present edition scarcely inspires us with feelings of gratitude. We are not prepared to admit that "No paranoiac loves his wife, or his brethren, or his friends in the right and normal way." The question of love is at best wholly a personal, individualistic possession, and it occurs to us that we have encountered more than one paranoiac, naturally not of the type "paranoia sexualis," who has loved his wife in a way to meet the approval of the latter. In referring to King Louis II. of Bavaria, Clouston says: "In him there appeared to have been sexual perversion of the most

abominable description. In this country we rarely see such cases as are described in such repulsive detail by Krafft-Ebing and Schrenck-Notzing, and I think it is better we should not look too closely for them." Better said: "This country furnishes the daily press, yearly or oftener, the most abominable and sickening details of such perversion in people of all grades of notoriety up to royalty, who, for the weal of the community, have to be sent to prison or to a modern Van Diemen's land." It would be better by far for the good of humanity if they were looked for closely, instead of pushing the head far enough into the sand to obscure vision.

We have quoted the designation "medical men" above, having in mind Clouston's XIX. Chapter "Medico-Legal and Medico-Social Duties of Medical Men, etc." Considering that a respectable minority of the asylum physicians in this country are not men, may we not reasonably ask the author to substitute the word "physician" in future editions, at least for the American edition? We can assure him that the "medical men" will not feel aggrieved and the medical women will be touched by his tacit recognition of their existence.

TWENTIETH CENTURY PRACTICE. An International Encyclopedia of Modern Medical Science. By Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In Twenty Volumes. Volume X.: DISEASES OF THE NERVOUS SYSTEM. New York: William Wood and Company. 1897.

THE contributors to the volume on nervous diseases of this series are few and with one exception all are American practitioners.

The fifteen-page index would indicate that the field has been well covered. The chapters are upon diseases of the brain, intracranial hemorrhage, tumors of the brain, diseases of the meninges, hysteria, epilepsy, spasmodic neuroses, neurasthenia, disorders of speech, and disorders of sleep. All of these authors write well and their productions make rather more fluent reading than some of the translations from foreign authorities. The two contributions from the pen of Charles Féré on hysteria and epilepsy have, however, been marred by no literal rendering of idioms, the translation preserving all original fluency of the French. The first two hundred and sixty pages are covered by contributions from Joseph Collins, of New York. The various subjects show evidences of painstaking care in their preparation. Following this, Charles L. Dana has an extremely well written and practical article on apoplectic conditions, followed by "Tumors of the Brain" from the pen of Bernard Sachs, also of New York, who has treated the subject in a masterly way. Howell Pershing, of Denver, has presented a chapter on the difficult subject of disorders of speech, covering the ground in a creditable manner. Sanger Brown, of Chicago, follows with "The Disorders of Sleep," the chief of which here treated of being insomnia, somnambulism, and nightmare. Dana has also contributed the chapter on neurasthenia, which is short and to the point. The spasmodic neuroses, including chorea and the various tics, are well described by Dr. Féré.

The volume is a worthy and valuable addition to this masterly series.

THE DISEASES OF THE STOMACH. By DR. C. A. EWALD. Translated and Edited by MORRIS MANGES, M.D. Second Revised Edition. New York: D. Appleton & Co. 1897.

THIS excellent book, which is so well and favorably known, has received many additions from the author as well as from the translator. Full mention is made of the newer literature of gastric pathology. Several new drawings have been added, thus the gastrodiaphane of Einhorn, the re-current stomach tube of Hemmeter, and a few drawings from Osler illustrating dilatation of the stomach. There is no doubt this book will be read and studied by the American profession with the greatest interest and much profit.

EXPERIMENTELLE UNTERSUCHUNGEN ÜBER DIE WIRKUNG RASCHER VERÄNDERUNGEN DES LUFTDRUCKES AUF DEN ORGANISMUS. Von DRS. RICHARD HELLER, WILHELM MAGER, HERMANN VON SCHROETTER in Wien. Bonn. 1897.

THE writers of this work arrive at the following conclusions:

The blood of the organism is not subjected to any mechanical changes under the influence of compressed air.

After a rapid liberation from the compression, free gas may be shown to exist in the blood-vessels. This gas consists principally of nitrogen.

If the stay in compressed air is a prolonged one and the liberation from it quite rapid, pathological changes arise which act either upon the function of the heart and lungs and may lead to death, or upon the nervous system.

All these pathological changes are caused by the presence of free gas in the blood-vessels, and may be partly subdued by the judicious application of compressed air.

PRACTICAL PATHOLOGY FOR STUDENTS AND PHYSICIANS. By ALDRED SCOTT WARTHIN, PH.D., M.D. Ann Arbor: George Wahr. 1897.

THIS work may be considered as an excellent guide for the student and practitioner in all laboratory and dissecting methods, giving them as practically as possible, but yet thoroughly and completely. With regard to the differential diagnosis of tumors, we cite the following from page 100:

"For the differential diagnosis of sarcoma or carcinoma in the gross specimen, the following points are to be taken into consideration: Sarcomata possess, as a rule, a smooth homogeneous surface, from which no cloudy juice rich in cells can be scraped. An uneven, granulated cut surface, in which a stroma of connective tissue may be made out, containing cell masses which are easily scraped away with the knife as 'cancer juice,' speaks for carcinoma. Yet for alveolar sarcoma this distinction cannot be made, its cut surface resembling in all points that of carcinoma. Squamous-cell carcinoma gives a dry cut surface, from which the grayish cell masses may be squeezed out like comedones."

CLINICAL LESSONS ON NERVOUS DISEASES. By S. WEIR MITCHELL, M.D. Philadelphia and New York: Lea Bros. & Co. 1897.

THIS little volume, from the pen of the "chief ornament of the medical profession in the States," as the University of Edinburgh styled him on the occasion of his enrolment among her favored few as the recipient of honorary degrees, will undoubtedly find a large and appreciative circle of readers both at home and abroad. There are in it that epitomization of years of bedside experience, that evidence of clinical insight, that fund and wealth of resourcefulness in the treatment of obstinate nervous diseases—as evidenced, for instance, in the chapter on sciatica—which convince that it is a book to be studied, to be assimilated.

It is commonplace to mention Dr. Mitchell's literary style, but there are choice bits in this volume that the talented author does not often surpass in his medical writings. To select one sentence taken from the chapter "Some Disorders of Sleep":

"In the borderland of coming slumber, when we are not yet overwhelmed by its full power, the steadying contradictions of the external world are, in a measure, by degrees cut off, while the will holds a slowly lessening rule."

The physician who strives for the caresses of fame, from a literary standpoint, be he neurologist, gynæcologist, or professor in a medical college, may see in these delightful and most instructive Lessons an unerring signpost. Devoid of the intricacies with which even attempt at completeness causes the customary treatise on nervous diseases to be beset, this collection of seventeen lessons must be a welcome accession to the readable books of every medical practitioner.

Dr. Mitchell's graciousness in preface and text to his physician assistants is a noteworthy, a gratifying, and a commendable feature.

MANUAL OF STATIC ELECTRICITY IN *X*-RAY AND THERAPEUTIC USES. By S. H. MONELL, M.D. New York: William Beverley Harison. 1897.

THIS interesting book contains over six hundred pages devoted to the value of the static current. Beginning with a description of the mechanism and *modus operandi* of the instrument, the author treats of the various ways of applying the currents, and gives valuable points for the correction of various errors in the management of the same. An elaborate series of chapters on the treatment of various disorders, such as "Neuralgias" and "Rheumatism," "Hysteria," "Headaches," "Locomotor Ataxia," etc., follow. It is almost incredible to find that the author recommends the static current for the treatment of gastro-intestinal disorders in infants; in fact, he describes two cases of infants, one a child

seven weeks old, in which he used the current with excellent results. This was for the relief of diarrhœa, but he says that he changed the diet and gave some internal medication besides the static current. The subject of *x*-ray photography is given in an excellent manner. This is the best part of the book. To those desiring information on this branch, the author gives his views in a clear and masterly manner. He has had abundant experience here and the work is to be commended for its treatment of this interesting subject.

DEATH AND SUDDEN DEATH. By P. BROUARDEL, Professor of Medical Jurisprudence, Dean of the Faculty of Medicine, Paris. Translated by F. LUCAS BENHAM, M.D., B.S. Lond. New York: William Wood and Company. 1897.

WITH a striking title and still more striking contents, this book is destined to command wide attention and extensive reading. Its inherent conception is novel and its adaptability to practical needs is everything that could be desired. There is in reality no work with which we are acquainted that so effectually covers the ground as does this one. There are, in fact, so many interesting and important facts mentioned in it which can be found nowhere else in such a convenient compass that the little book has an intrinsic value. It represents a course of lectures on forensic medicine delivered by Brouardel and admirably translated by the English editor. In part I., under the signs of death, the author treats of the moment of death, of the uncertainty of some of the signs of death, and of the absolute proofs of the actual occurrence of death. The dangers of premature burial in cases of apparent death are fully set forth. It is comforting to such as may have exaggerated notions of the frequency of premature burials to know that the chances of such mishaps are reduced to the minimum, in fact are made impossible when the death is scientifically established. In estimating the relative value of the signs, that of cessation of heart beat ranks first, although the reader will be surprised to learn that cardiac action can be excited after a cessation of three hours in the stillborn. The reference to several illustrative cases of apparent death for hours and final resuscitation makes very interesting and instructive reading. The phenomena of decomposition are very graphically presented and many instances are related in which the cadaveric ptomains have in medico-legal cases been mistaken for ingested poisons. Part II. treats of the causes of sudden death as centred in the different vital apparatus, and many instructive instances are related of some curious forms of sudden death, the occurrence of which would not have been suspected without post-mortem examination. The concluding section is on sudden death in children, which forms a distinctive feature in a work which is instructive and interesting from beginning to end. We venture to say that no physician can read it without profit or consult it without benefit.

CONTRIBUTIONS TO THE PHYSIOLOGY AND PATHOLOGY OF THE NERVOUS SYSTEM. By ISAAC OTT, M.D.

THIS little brochure contains essays on the thermogenic centre in the tuber cinereum; effect of section of the vagi upon temperature, heat production, and heat dissipation; notes on the animal extracts; the rhythmic action of the bladder, effect of certain drugs upon it—the original publication of which materially helped to establish the writer's reputation as a physiologist.

ILLUSTRATED SKIN DISEASES. An Atlas and Text-book. By WILLIAM S. GOTTHEIL, M.D. New York: E. B. Treat, 1897.

PART IV. treats of the acute "exanthemata, morbilli, rubeola, scarlatina," etc. These are treated only from the point of view of the skin eruptions that characterize them. Varicella and variola are illustrated from typical and well-marked cases. The picture of vaccinia rash, on page 91, calls attention to a fairly common but little noticed general eruption. The same part and the next one contain the section on favus and ringworm, and are appropriately illustrated. Figs. 49 and 51 are especially good, representing ringworm and pitiriasis rosea. Part V. deals also with the parasitic skin diseases of animal origin and we note in them some excellent micro-photographs. The large section of eczema concludes Part V., and fills the first pages of Part VI. This important subject is represented in a number of photographs representing all its various stages and forms. Pemphigus, impetigo, and exfoliative dermatitis occupy the remainder of this part, the concluding pages being devoted to psoriasis. The color plates represent ichthyosis, keratosis, and zoster. It is interesting to note that almost every picture is from an original photograph. The parts are filled with practical information, and give very valuable prescriptions for the management of the various disorders treated. These three parts show an expenditure of great labor, and the author is certainly to be complimented on the successful result. The type is very clear, and the illustrations are large and distinct. In connection with this work we may say that it is a matter of wonder to us where the publishers of the numerous atlases of skin diseases issued the past few years can find profit. Hardly is one completed than another is begun. There are too many books published.

FIRST AID IN ILLNESS AND INJURY. By JAMES PITCHER, M.D., PH.D., Captain in the Medical Department of the United States Army. New York: Charles Scribner's Sons. 1897.

THIS work is probably the best of its kind ever brought out. The subject matter is set forth in clear and intelligible language, and the use of technical terms is avoided as much as possible. The illustrations are copious and good, and altogether the work is one that will prove useful in any household.

DISEASES OF THE EAR, NOSE, AND THROAT, AND THEIR ACCESSORY CAVITIES. A Condensed Text-book. By SETH SCOTT BISHOP, M.D., LL.D., Professor in the Chicago Post-Graduate Medical School and Hospital, Surgeon to the Illinois Charitable Eye and Ear Infirmary. Philadelphia and New York: The F. A. Davis Co.

THIS work, which is comprised in four hundred and ninety-six pages, is excellently printed and fully illustrated. It is designed to be of use to a large number of medical men, the student, the practitioner, and the specialist in his early studies. The author has endeavored to bring the work fully up to date, and much prominence is given to the consideration of recent advances in the knowledge of diphtheria and serum therapy, also to descriptions of recent surgical appliances. The first chapter is devoted to a statistical study of twenty-one thousand cases of diseases of the ear, nose, and throat. The descriptions of the conditions met with are characteristic of the author, clear and not too full. The specific definite manner in which the forms of treatment advocated are given makes the information valuable to the student and practitioner, and the number of methods and remedies mentioned is not sufficiently large to be confusing. The statement regarding the introduction of sprays and medicated vapors into the ear by means of tubes that do not enter the nasal cavities beyond the anterior nares would with the hypercritical raise the question as to what becomes of the residual air, and suggests an undue strain on the law of the diffusion of gases. A number of extravagant expressions are found. The style in parts might, perhaps, be criticised. Facetious phrases are sometimes met with. These features serve to illustrate the well-known personal peculiarities of the author, but they do not detract from the value of the information given.

INEBRIETY, ITS SOURCE, PREVENTION, AND CURE. By CHARLES FOLLEN PALMER. Fleming H. Revell Company. 1897.

IN this small volume the author, in a clear, easy style, discusses what he calls the nervous-mental organization in its causal relation to inebriety and allied manifestations of an abnormal nervous system, and draws the following conclusions: "Alcoholic inebriety is often based upon and dependent on diseased conditions which demand proper medical or hygienic treatment for their removal. The inebriate is a diseased person, and the disease has either preceded the inebriety or is dependent upon it." He believes in the possibility of altering the constitutional temperament by suitable training of the affected individual, preferably from earliest youth. This is to be accomplished by the choice of such physical, mental, and moral hygiene and exercise as tend to make a hardy, vigorous organism, and especially by the rigorous and systematic strengthening of the moral will power and self-control. He deems absolute abstinence from all

stimulants and narcotics an essential to the prevention or cure of inebriety in the disease type of individual under discussion. The author will probably be deemed oversanguine as to the results obtainable in the majority of cases, but his book contains many helpful suggestions for the treatment of neurotics in general, as well as those who are predisposed to alcoholism.

HYSTERIA AND CERTAIN ALLIED CONDITIONS. Their Nature and Treatment, with special Reference to the Application of the Rest Cure, Massage, Electro-therapy, Hypnotism, etc. By GEORGE J. PRESTON, M.D., Professor of Diseases of the Nervous System, College of Physicians and Surgeons, Baltimore; Visiting Physician to the City Hospital, etc. Illustrated. Pp. 298. Philadelphia: P. Blakiston, Son & Co. 1897.

THIS is an exceedingly attractive little book, and, although it may not contain much that is new to the specialist, is a valuable contribution to the voluminous literature of a familiar subject. It will be especially useful to the general practitioner, for whom, indeed, it is intended. The introductory historical chapter is quite interesting. The next two on etiology and pathology, and on symptomatology, are admirably clear and succinct. Chapters IV. to VIII. (inclusive) deal with motor disturbances, convulsive attacks, mental conditions, and visceral and vasomotor disturbances, and are well illustrated by plates and diagrams from Richer, Charcot, and de la Tourette. Three chapters are devoted to treatment, in which the advantages of massage, electro-therapy, and the rest cure are thoroughly discussed. Hypnotism receives due attention. With a concluding section on the surgical treatment of hysteria we are heartily in sympathy, especially the final sentence, viz.: "The rule, then, that should be adopted is that operations should not be performed on hysterical women for the relief of the nervous symptoms, unless some distinct disease of the reproductive organs can be detected."

LECTURES ON THE TREATMENT OF FIBROID TUMORS OF THE UTERUS, MEDICAL, ELECTRICAL, AND SURGICAL. By FRANKLIN H. MARTIN, M.D., Professor of Gynæcology, Post-Graduate Medical School of Chicago, etc. Pp. 174. Chicago: The W. T. Keener Company. 1897.

THIS little monograph includes a series of ten lectures, which present an excellent *résumé* of the most recent views on the subject of the treatment of this class of tumors. The first five chapters (sixty-five pages) are devoted to anatomy, pathology, and non-surgical treatment; the last five to descriptions of various operations, especially hysterectomy. The latter are excellent, and are well illustrated. Chapter VII. deals with the author's operation of ligating the uterine arteries, which he may be pardoned for making rather longer than its importance would seem to warrant in comparison with other more radical procedures. The style is clear and pleasing, and the little book will well repay a careful reading, especially by the general practitioner.

ORGAN DISEASES OF WOMEN, NOTABLY ENLARGEMENTS AND DISPLACEMENTS OF THE UTERUS AND STERILITY, CONSIDERED AS CURABLE BY MEDICINES. By J. COMPTON BURNETT, M.D. Pp. 156. Philadelphia: Boericke & Tafel. 1897.

IF it were not for the fact that our homœopathic friend takes himself so seriously, we should be inclined at first sight to regard this little book, like its title, as a medical joke. But the author is certainly an original character, as shown by his epigrammatic style and decided opinions. He sets his face firmly against Malthusian doctrines, and records triumphantly at the conclusion of most of his cases that "a bonnie boy" was the result of his purely medicinal treatment. It is difficult to pass judgment on views from which we differ so essentially, but even from a purely common-sense standpoint one is forced to conclude that the writer "doth profess too much."

ATLAS UND GRUNDRISS DER LEHRE VOM GEBURTSAKT UND DER OPERATIVEN GEBURTSHILFE. Von DR. OSKAR SCHAEFFER, Privatdocent an der Universitat Heidelberg. IV. Auflage. München: Verlag von J. F. Lehmann.

THE fourth edition of this well-known work has been thoroughly revised, and many additions have been made, especially in the section devoted to operative obstetrics. We note a new page on symphyseotomy, though it is to be regretted that there are no accompanying illustrations. The same comment applies to the new subject matter on *accouchement forcé*, a procedure which has assumed considerable prominence of late.

Of course the most valuable part of the book is the pictorial. The plates have been of the greatest assistance to generations of medical students and practitioners, and will not easily be superseded. The graphic representation of the more common obstetric operations (forceps and version) are beyond criticism. We are happy to add that through the enterprise of William Wood and Company this work, as well as the companion, "Essentials of Gynæcology," have been made familiar to non-German readers.

ATLAS AND ESSENTIALS OF GYNÆCOLOGY. By DR. OSCAR SCHAEFFER, Privatdocent in Obstetrics and Gynæcology at the University of Heidelberg. With 173 Colored Plate Illustrations and 54 Woodcuts. Pp. 288. New York: William Wood and Company. 1897.

TO say that the publishers of this translation of Schaeffer's work have improved on the original in their colored reproduction of the plates is sufficient commendation. When we add that the terse condensed style of the author has been closely followed without the sacrifice of good English, we have said enough to convince those familiar with the latest German edition that American students have now within their reach a most valuable aid in their practical work in gynæcology. Though praise of separate plates would be invidious, we are especially pleased with those representing the various forms of malignant disease of the portio and uterine displacements. The plate facing page 20, and those showing different varieties of fibroids, are also worthy of commendation.

The work of the translator is certainly deserving of praise. The reversal of the original order (the text being first in the German), and the tables of contents and of illustrations, are decided improvements. The type, binding, and *tout ensemble* of the American edition are unusually pleasing to the eye.

SYRINGOMYELIA: The Alvarenga Prize Essay of the College of Physicians of Philadelphia for 1895. By GUY HINSDALE, M.D. Philadelphia: P. Blakiston, Son & Co. 1897.

THIS essay has already appeared in the columns of the *International Medical Magazine*. It is now republished with some slight additions, a dedication, and an appendix.

Dr. Hinsdale treats his subject historically, as becomes a prize essay, and then considers the causation, symptoms, outcome, etc.; but it cannot be said that he has done so exhaustively. Although there is a very lengthy bibliographical appendix, the text does not convince one that the wealth of material indicated by this appendix has been carefully and comprehensively digested. The discussion of the pathogenesis of syringomyelia, its development, and even its morbid anatomy are by no means what they should be in a prize essay, particularly when it is borne in mind that the author has made no contribution to the subject save two very brief clinical histories. Although the monograph bears many evidences of haste and loose construction, in a general way it gives a fairly good *résumé* of the subject, and for those not familiar with German literature it may be recommended as the most lengthy exposition of the subject in English.

THE AMERICAN YEAR-BOOK OF MEDICINE AND SURGERY. Being a Yearly Digest of Scientific Progress and Authoritative Opinion, drawn from Journals, Monographs, and Text-Books of the Leading American and Foreign Authors and Investigators, under the General Editorial Charge of GEORGE M. GOULD, M.D. Philadelphia: W. B. Saunders, 1897.

THIS year-book, like several others of a similar kind, essays to solve the extremely hard problem of how to present a sufficient and critical digest of contributions to every branch of medico-surgical literature that have been published during the preceding year. The endeavor to cover the whole range of medical science within the limits of one volume, however bulky, presents in many ways almost insuperable obstacles. So far as the particular book under notice goes, it is well compiled, but its scope of usefulness and that of all year-books is necessarily a restricted one. This boiling-down, so to speak, of the medical work of an entire year is attended

with many drawbacks. To epitomize properly the medical and surgical writings of so long a period is nearly impossible. Dr. Gould's year-book is probably as successful an attempt as has been made in this direction. To criticise the book in detail would be to attempt a task beyond the powers of any one individual, so that no decided opinion can be given as to whether the subjects dealt with have been judiciously selected or appropriately touched upon. Judging from a somewhat cursory perusal, the chosen portions appear to provide as nourishing literary food as can be expected.

A few changes have been made in the names of those in charge of some of the departments, but on the whole the editorial staff remains the same as that of the issue of last year. It is our judgment that the days of usefulness of all "year books" are past, and that their continued arrival is in the nature of "pot boilers," by both editors and publishers. No wideawake physician needs books of this sort, for he keeps himself better informed by means of his weekly journals.

APHASIA: The Cerebral Speech Mechanism. By WILLIAM ELDER, M.D., F.R.C.P. London: H. K. Lewis. 1897.

THE writer of this treatise is known to the readers of medical literature from a remarkable contribution which he made to the subject of aphasia, published in the Edinburgh Hospital Reports a short time ago. The greater part of the present volume is the author's thesis for the M.D. degree of the Edinburgh University.

The author shows his familiarity with modern literature, especially that of the school of Déjerine, from the writings of which he has evidently got much inspiration. The burning questions in the subject of aphasia to-day are, first: Is there such a territory as the speech area? second, If there be, are there four definite centres, one for articulate speech and one for written speech, constituting the motor side of language, and an auditory and visual centre constituting the sensory, receptive side of language? It is well known that this was the conception of Charcot and the great majority of writers since the former gave it to the medical world. During the past decade, however, there has developed a school, headed by Déjerine, which refuses to follow Charcot's dictum in the face of absolutely contradictory evidence, and deny the existence of a graphic motor centre, while affirming the existence of one receptive speech area, injury of which in any part will invariably entail some disorganization of internal language. After reading Elder's chapter on agraphia and the question of the existence of a graphic centre, it seems to us that he denies such existence; yet when we turn to page 55 we find that such a centre is beautifully delineated in colors occupying the area to which Exner, in one of the most unscientific contributions ever made to medicine, allotted it, and on which Charcot based his teaching of the existence of this centre, and which Bar thought he corroborated by the publication of his case.

Space prevents us from an analysis of this very interesting book of Elder. Its most serious fault seems to us a deficiency in the critical faculty and evidences of too close study of Wyllie's recent work, which we regret to say we cannot believe is "the most accurate and comprehensive account of the whole subject that has yet been published," as it appears to Elder. Those who are familiar with the subject of aphasia will have much pleasure and profit in the perusal of the book before us, while those who are not familiar with the subject will get some of both.

Diagnosis of Small Ovarian Tumors.—Dr. Davenport (*Boston Medical and Surgical Journal*, 1896, No. 15) concludes his article with the following propositions: 1. Small intrapelvic growths give rise to marked symptoms. 2. Pain is usually noted, but does not bear a constant relation to the location or kind of tumor. 3. Menorrhagia or metrorrhagia is frequently present, especially in cases of cystic ovaries adherent to the uterus. 4. When uterine hemorrhage exists in connection with an intrapelvic tumor, and is not affected by intra-uterine treatment (curettage or electricity), the tumor is probably ovarian rather than uterine. Reflex symptoms are rare with small tumors, at least in the earlier stage of their development.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON GENERAL SURGERY

Stated Meeting, May 10, 1897.

W. W. VAN ARSDALE, M.D., CHAIRMAN.

Stab Wound of Abdomen; Perforation of Intestine; Suture; Recovery.—DR. P. R. BOLTON, in presenting the patient, said that one point which the case illustrated was the usefulness of salt solution on the peritoneum. The patient was a man of twenty-six, who had been brought to the Hudson Street Hospital last September, very soon after having received a stab of the abdomen. There were marked shock and a wound in the abdomen about four inches in length on the left side, through which there protruded a mass of intestines well smeared with fæces. The wounds of the intestine were found and sutured, and salt solution was used very freely both before and after reduction of the intestine. The usual antiseptics were employed for the abdominal wound, and this was closed. It was interesting to note that within the abdomen, where only salt solution was used, no inflammation or trouble followed; whereas at the abdominal wound, where bichloride, etc., were used, suppuration took place. The patient made a good recovery, with some weakness of the abdominal wall, over which he now wore a bandage.

Nephrectomy, Subsequent Uretero-Lithotomy on Opposite Side.—DR. F. KAMMERER showed a patient, aged thirty-one years, upon whom he had, in the summer of 1895, performed nephrotomy and nephrectomy on the right side for a large renal calculus and degeneration of the substance of the kidney. The patient had done very well for one and one-half years following these operations, and had gained thirty pounds in weight. Although she had previously suffered for several years from renal colic on both sides, she had never had any pains on the left side since the operations in 1895. In February, 1897, the speaker saw her again, and she gave the following history: She had had severe pains on the left side for the past two weeks; very little urine had passed during the last week. She was nauseated at times and feverish. On examination the left kidney was rather sensitive to the touch. She was watched for a few days, but when anuria had been noted for thirty consecutive hours an incision was made, exposing the pelvis of the left kidney in the lumbar region. After incising the ureter near the pelvis, a stone the size of a bean was discovered, about four inches from the junction of the ureter with the pelvis, which was after some exertion pushed toward the incision in the ureter and removed. The pelvis of the kidney was drained through an incision in the kidney substance for two weeks, and the kidney irrigated with normal salt solution. The incision in the ureter was closed on the fifth day with catgut sutures. In about two months the entire wound had closed. The urine still contained some pus, but no renal elements.

Lithotomy, Common Bile Duct.—Dr. Kammerer also presented a woman, thirty years old, who had always been healthy, and had had four children. Her first illness began seven months ago, when she had a typical biliary colic. Severe attacks had occurred off and on for the last seven months. For the past six months she had had increasing jaundice; urine dark, stools clay-colored. Not having been benefited by any internal treatment, she was referred to the hospital for surgical interference. She had never passed stones to her knowledge. She was fairly well

nourished; icterus was intense and the liver was enlarged. From the history and examinations it was evident that some obstruction existed in the common bile duct, but excepting the enlarged liver palpation proved negative. The transverse incision according to Courvoisier, parallel and about one inch above the border of the liver, was made; there were extensive adhesions about the gall bladder, which latter was finally exposed by separation of the former. The attempt to separate the pylorus and duodenum from the cystic duct, in order to expose the latter, proved futile. The adhesions between the organs mentioned were so dense at this point that the somewhat distended cystic duct suddenly gave way during manipulation, and a large quantity of bile was discharged through the rent thus produced. A probe passed into the duct was arrested at a distance of two and one-half inches (in the common duct). Further attempts to separate the pylorus and duodenum were also in vain, as the parts were so densely enveloped in adhesions that they could not be differentiated from one another at this point. The stone, on the other hand, could be distinctly felt through the walls of the stomach. All attempts to dislodge the stone from the opening in the cystic duct failed—forceps, spoons, hooks, etc., being used. After a great deal of manipulation and the use of an amount of force scarcely warranted, the stone was finally moved by pressure upon the walls of the stomach and ultimately delivered through the rent after the latter had been considerably enlarged. It was of about the size of a small walnut. The opening in the cystic duct was now closed with catgut sutures, and Murphy's tube introduced into the gall bladder for drainage, alongside of which a tampon was pushed to the point at which the cystic duct was sutured. The patient made a slow but uninterrupted recovery, complete healing being accomplished in about six weeks.

The interesting point in this case was the dense adhesions of the digestive to the bile tract. The time consumed in the delivery of the stone was almost one hour, and the speaker thought the pressure exerted upon the stone through the wall of the stomach was very great. But he did not think any one would advise incision of the stomach to get at the common bile duct, which otherwise would have been a necessity in this case, owing to the changed anatomical relations of the parts, although the procedure by incision had been eminently successful when the duodenum was the viscus covering the common bile duct (Kocher).

Drainage of the Kidney and Pyrexia.—Dr. Samuel T. Alexander remarked, in relation to the fall of the temperature in Dr. Kammerer's case after removal of the drain leading to the kidney, that he had in several cases found pyrexia persisting after operations upon the kidney until the drainage tube had been withdrawn from the kidney.

The Chairman asked whether iodoform gauze had been used in all of these cases, and Dr. Alexander replied that it had not been in all.

Dr. Walker's observation had confirmed that of Dr. Alexander.

Dr. Kammerer thought the question of getting the wound leading to the kidney and that in the kidney to close would depend much upon the condition of the kidney. In the same case, one kidney the seat presenting stone without suppuration, the other with suppuration, no difficulty might be encountered in securing healing on the one side, but there might be great difficulty on the side of pyelitis.

Dr. Alexander had recently induced healing by the use of one of the ozone solutions, in a pus pocket in the kidney, which had been found to be the cause of persisting sinus.

Wound Infection by the Bacillus Aerogenes Capsulatus.—The paper was written by Drs. John Erdman and H. R. Brooks, and was read by the former. It was in 1891 that Dr. William Welch published an article in which he described the bacillus aerogenes capsulatus and the method of its cultivation. Dr. Welch had also contributed to the subject subsequently, and twenty-three cases, not all of them surgical, had been described in which this bacillus was found. Its habitat was thought to be the soil, and Dr. Erdman believed it was often present in the intestine, from whence it found its way to wounds. The infection might be a simple or a mixed one. An analysis of the cases of Welch, Flexner, and Dunham would seem to show that recoveries had been confined to the cases of mixed infection. In these, pus was usually present. The infection might take place through the circulation or through instruments. Among the symptoms which arose when the wound became infected by the bacillus aerogenes capsulatus were rapid pulse, rise of temperature, delirium, discoloration of the area involved, emphysema of the tissues, and rapid distention of the abdomen when the peritoneal cavity was involved. The rapidly developing delirium, stupor, and somnolence seemed to be due to toxæmia. Incision and drainage, and it might be amputation, were indicated.

The authors reported one case which had come under their observation, and in which the bacteriological report was made by Dr. Dunham. In a fall the patient had sustained compound fracture of the right humerus, contusion of the shoulder, and slight scalp wound. The infection of the arm wound by the third day by the bacillus aerogenes capsulatus was attended by increased pulse, temperature, and respirations, and delirium soon developed. The emphysematous condition of the tissues soon extended to the chest, so that amputation of the arm was deemed improper. The patient died three days after the original injury and one day after the infection alluded to.

A summary of the cases of Welch and Flexner which had a surgical bearing, and of others, including that of Dr. Bryant, brought the number up to sixteen. Four patients recovered. Two cases were of pure infection, and in both of these the patients died. In the others the best results were obtained when amputation was resorted to. The most frequent mixed infection was with the streptococcus; in a number there was the bacillus coli communis. In their conclusions the authors stated that, in view of the frequency with which the bacillus aerogenes capsulatus occurred in the peritoneal cavity and its association with the colon bacillus, they were justified in believing that its habitat in man was in the intestinal tract. When introduced from without it was probably from the soil. The mixed infection was not so grave. This suggested a possible treatment by an antitoxin serum or germ infection. The surgical treatment was by free incisions, with drainage or amputation. Dr. Halstead had brought out a treatment by immersion in a bath, which Dr. Dunham would comment upon.

Dr. E. K. Dunham opened the discussion, and confined his remarks chiefly to points suggested by the treatment which Dr. Halstead said he now applied to cases of infection, placing the patients in a full bath of warm water—96° to 98° F. The water was renewed at intervals of about two hours. He claimed excellent results from this treatment in various forms of infection, including one or two cases of infection from the bacillus aerogenes capsulatus. He was unable to give Dr. Dunham a good explanation of how the bath acted, but it seemed at least to promote the discharge of the poisons from the wound. In view of these facts, Dr. Dunham had made a number of experiments with the bacillus aerogenes capsulatus. The bacillus was a strict anaerobe, or incapable of growing in free oxygen. It had occurred to him that one might

take advantage of this fact to prevent or check infection by exposure to oxygen. In certain culture tubes he freed the bouillon of oxygen, in others exposed it to oxygen. The bacilli developed in the former, and little or not at all in the latter. When they did get a start, the evolution of gas in their development still further favored their growth. This became apparent in experiments with pieces of the liver of an infected animal, the evolution of the gas within the tissue causing it to rise in the water in which it was submerged. This did not occur with pieces of the kidney, which would seem to show that the sugar in the liver favored this gas formation. Perhaps it would not be so in life, as the liver might then possess inhibiting influence upon the bacilli. Just how much oxygen the blood might carry to act as an inhibiting influence on the growth of the bacilli in the tissues was a question. The experiments would seem to point to the wisdom of getting rid of the dead tissues as quickly as possible, since they favored the development of these bacilli, and to expose them as soon as possible to oxygen. Regarding Dr. Erdman's statement that the cases of mixed infection had been least virulent, it was not yet safe to draw the conclusion from this fact that the presence of the other germs rendered the bacillus aerogenes capsulatus less virulent. On the contrary, the latter was known to possess varying degrees of virulence in pure culture, and when the conditions were not favorable it did not grow. Now necrotic tissue with the presence of other germs might cause the less virulent germs to grow, whereas if these conditions were absent they would not develop at all. In Dr. Erdman's own case, this bacillus was not very virulent; Dr. Dunham had been unable to kill a guinea-pig with it.

Kidney Tumors Derived from Suprarenal Rests.—Dr. P. R. Bolton read the paper and gave the history of a case. The classification of these tumors was, he thought, in a state of chaos. There was little American literature on the subject. The gross and microscopic appearances of the tumor in his case were studied by Dr. Warren Coleman. The patient was an Englishman, fifty-six years of age; family history negative; he had had African fever ten years ago. He had noticed a mass in his left side for a year. The urine was dark red and contained albumin, many blood clots, and a few casts. Having ascertained that the other kidney was sound, Dr. Bolton removed the tumor, which involved the kidney and capsule. The diameters were fourteen, eleven, and nine and one-half centimetres. The visible surface of the kidney measured five, four and one-half, and three and one-half centimetres. At one point of section there was distinct connective-tissue limitation between the tumor and the kidney. So far as the examination had proceeded no part of the kidney was involved by new tissue, but the kidney was the seat of chronic diffuse nephritis. The tumor contained roundish, yellowish, small opaque masses, surrounded by irregular fibrous stroma and larger and smaller hemorrhages. No opinion had yet been formed of the nature or origin of the tumor, but so far as the examination had proceeded it was independent of the kidney proper. Speaking of tumors of the suprarenal capsule in general, Dr. Bolton said they were either benign or malignant, but even in cases showing distinct characters of cancer the patient might live several years. Out of thirty-five cases the male sex was affected in twenty-two, the female sex in thirteen. The age had varied from two and one-half to seventy-nine years, but in the majority of cases it was over forty. The right and left kidney had been affected about equally. Metastasis had occurred into various organs. The treatment, when possible, was nephrectomy.

Dr. Dunham said he had met with only one case of tumor of the kidney which he thought had its origin from the adrenal body. It was of very small size, and attracted attention only at autopsy.

Section on General Medicine.

Stated Meeting, May 18, 1897.

Louis F. Bishop, M.D., Chairman.

The Composition of Cream and a Consideration of the Desirability of Establishing a Standard.—Dr. J. H. Huddleston read a paper on this subject. In 1896 the city consumed about nine million quarts of cream. It came from within a distance of three hundred miles. About half of it was consumed by families, the other half by ice-cream factories, bakeries, etc. The former usually received it in bottles, the latter in cans. The bottle method was best if the bottles were properly cleansed; otherwise it was the worst. The cream was called gravity cream when collected by allowing the milk to stand and the cream to rise; separator cream when separated from the milk by some one of the centrifugal machines. The latter method was the quickest way of collecting the cream, the gravity method requiring about twenty-four hours for the cream to rise to the surface. But this length of time seemed to be of little consequence in the minds of the dealers, for they usually retained the cream some days, even a week or longer, as age added to its thickness and therefore apparently to its richness. It had been shown that this thickening from age was due to the multiplication and action of bacteria in the cream. There was no standard richness of cream. Dealers supplied only two kinds, what they called light and heavy cream. For the latter they charged considerably more, but the amount of fat which either kind contained was variable. This was probably due to the fact that there was not yet a well-considered plan as to cream tested by fat quantity. For instance, the dealer might sell a can containing a certain number of quarts, say forty, which he estimated would produce a certain number of pounds of butter, say thirty-five, but when this had been tested the amount of butter obtained had not corresponded with the estimated amount by a number of pounds. One could not tell the composition of the cream by its appearance, for the same cream presented a different appearance according to its age, etc. The effect of sterilization or pasteurization was to make the cream appear thinner, for the reason that germ growth was checked. But sterilization made it unsuitable for some purposes, and pasteurization as usually carried out left a considerable number of bacteria. Still, such cream kept longer than that which was not pasteurized. If the temperature were carried above 70° C. the cream would have somewhat a cooked taste. The regulations of the board of health required that milk sold in the city should conform to certain tests. Skimmed milk could not be sold. The author thought the people should be able to purchase cream of a certain fat test, and suggested the possibility of a plan to supply certified cream similar to the plan of Dr. Coit for supplying certified milk in Newark. Such cream could be of any desired fat quantity and of known age.

Dr. Hubbard, secretary, read a letter from Dr. Henry Coit, of Newark, regretting his inability to be present, and suggesting as one requirement for certified cream a fat percentage.

Dr. R. G. Freeman thought that since cream was usually valuable in proportion to the amount of fat which it contained, and this amount varied so greatly in substances sold under the name cream, there ought to be some standard. Cream which was collected by

the old process would require to be tested, but it was likely that that which was collected by centrifugal machines would usually come up to the regulations, so many quarts of cream to so many quarts of milk, allowing that the latter conformed to the requirements of the health department. He understood that the standard for milk had been placed so high in Boston that dealers had found it necessary to take all their milk to a central station and mix it to avoid any portion falling below that standard. Of course this required manipulation. The less manipulation which milk received the better for it. The ideal method was to have milk properly bottled at the dairy and not opened until it reached the consumer. It gave less chance for contamination. He agreed with Dr. Huddleston, that skimmed milk had a certain nutritive value for the healthy and sick, and at present a great deal was thrown away at large dairies because it was not allowed to be sold in this city. He thought it ought to be permitted to enter the city and sold at some price as skimmed milk. Regarding pasteurization of milk in large plants, he thought that had injured the reputation of pasteurization, for as thus carried out, in some plants at least, the milk was raised to a certain temperature and almost immediately cooled. It was far more effectual to keep that temperature for from fifteen to thirty minutes. A temperature of 68° C. for thirty minutes was more effectual in sterilizing milk than a momentary temperature of 80° or 90° C., and, of course, it changed the taste less.

Dr. L. Emmet Holt felt that every time the subject of the milk and cream supply was brought up, new impulse was given toward securing a clean and reliable supply of these nutritive fluids. At present there certainly was the greatest possible variation with regard to the cream, and he supposed it was because there had not yet been sufficient demand for a cream of a definite standard. He thought it did not make so much difference just what figure was taken, whether fifteen or twenty per cent., only that there should be some standard. Perhaps twenty per cent. would be the nearest for our supply, and would change the price least. With regard to skimmed milk, it certainly was valuable in certain conditions. He had been experimenting with it in certain intestinal disorders and typhoid fever in children, with extremely good results, especially after peptonizing it.

Dr. W. L. Stowell said there were two sides to the question, the one the commercial, the other the scientific or food value. It certainly made a difference to a person from the point of view of nutrition whether what he purchased contained twenty-five or whether it contained only fifteen per cent. of fat. Heavy cream contained forty to forty-two per cent. Light cream which he had tested contained fifteen to twenty per cent. Most cream supplied to the city was centrifugal cream. It ought to be certified as to the percentage of fat and the purity of the milk from which it came. On the same farm the surroundings of the horses might be found models of neatness, while those of the dairy cows were dirty.

Dr. H. G. Piffard said criticism had been offered upon the double standard required for milk sold in this city, that of the fat test and the test for solids. They did not correspond. For practical purposes he thought the fat test was sufficient, it could be applied more easily. He would make it higher than that required at present, for the average milk in the district from which New York received its supply contained 3.75 per cent. of fat. When cows failed to give milk of that standard the farmer should sell them to the butcher and replace them by those which gave richer milk. He had read that some dairymen in the West would not think of keeping cows which gave less than four per cent. fat. Perhaps dealers would do as they did in Boston, pool their milk, but that could be prevented by occasional tests being made at the farms. Dr. Piffard also referred to the value of skimmed milk, and said that much of it was thrown away, though much was returned at creameries to farmers who fed it to their stock. As it was there pooled, he had in a paper called attention to the necessity for sterilizing it to prevent spread of tuberculosis. Regarding cream, Dr. Piffard thought there should be legislation prohibiting dealers from holding it back or selling it after it was a certain number of hours old, prohibiting the use of preservatives, and requiring a standard for butter strength.

E. Nelson Ehrhart spoke upon the subject of dairies and means of securing pure milk in general. He had been engaged to analyze the milk and point out necessary changes in several dairies, and was convinced that here was a field for educated and practical men. Some such system of preventing contamination of milk as that employed in Copenhagen was desirable. In talking with Mr. Martin, of the board of health, he had been informed that the sale of skimmed milk had not been allowed through fear dealers would mix it with other milk. It would seem, however, that licensed dealers ought to be permitted to sell it as skimmed milk, for it possessed food value.

Dr. W. L. Baner had tested the taste of gravity and centrifugal milk, and his preference had been expressed for the former. For some reason the taste was altered somewhat by centrifugal separation.

The Methods of Infection in Malarial Disease.—Dr. J. Richard Taylor read this paper. The first part was devoted to a brief statement of views expressed in comparatively recent papers, including Daily's, R. C. Newton's, Thayer and Hewetson's, Manson's, Darlington's, etc. Sternberg held to the old view of inhalation of marsh miasm; Daily advanced the idea that infection was through drinking-water; Manson held that man was the alternate host, from which the germs must escape in order to complete their life cycle, and this was by agency of the mosquito.

House Plants and Malaria.—Just after the Christmas holidays Dr. Taylor was called at Sag Harbor to a woman eighty-two years old, who had some paroxysms of fever with gastric disturbance, and at her suggestion that it might be malaria he examined the blood and found the Lavaran plasmodium. This was remarkable in view of the facts that the ground was covered deeply with snow, the patient had not been from home for four years, the well water could not have been contaminated, all ponds were frozen. Soon a daughter had similar symptoms. There were some potted plants in the house, and he was unable to make any definite impression upon the disease until these had been removed. At the same season, a third case developed in another house in which a trap door led into a cellar whose walls were covered continuously with mould. In still another house some weeks later, in the same town, malaria with the plasmodium of tertiary fever developed in a child, and no apparent cause could be found except the potted plants in the room occupied by the patient. When these were removed he was able to cure the disease. He then went to some florists in localities where there were no marshes, and where they were not likely to be infected by the water supply, and inquired their history and made blood examinations. He found in four different localities that the blood of these people contained the malarial plasmodium. These florists were not ill, but they were hardly ever quite well, complaining of digestive trouble, headache, and indefinite symptoms. They could be straightened up temporarily by a big dose of quinine.

Dr. Taylor then gave his personal experience when in Charleston. He took precautions about the drink-

ing-water to avoid filaria sanguinis hominis, and when he rode out he took the precaution to return early before the mists rose from the marshes. During this time he kept well, but later, not having time to ride until rather late in the evening, he contracted pernicious intermittent fever. He could then find the malarial plasmodium in his blood. From 1879 to 1883 he resided in the mountains of Colorado, and saw what he supposed had been called mountain fever, but all the cases which he saw were tertian intermittent fever. A German writer had spoken of a similar fever developing in the mountainous regions of Russia, at the time of the melting of the snow. This was in harmony with what he had seen in Colorado. But at Sag Harbor the snow was not melting and the region was not mountainous. There was no bad water to explain the malaria and the presence of the malarial body in the blood. These facts would seem to point to something emanating from the plants, or rather from the earth itself, as one of the surest means of infection. Yet the water theory should also be borne in mind. Some observations relating to the water system of Sag Harbor during one period pointed in this direction, but in the cases related above the water was not obtained from that system.

Dr. H. G. Piffard referred to the sudden development of chills in tuberculosis which sometimes simulated malaria, but the changes in the blood were different. In connection with treatment, he spoke of the value of Alonzo Clark's combination of ten grains of quinine and six of capsicum; also of boneset, fluid extract of the fresh plant. Regarding the plasmodia, which were supposed to take twelve or twenty-four hours to pass through their stages, he could not harmonize this view with the occurrence of chills within three hours after exposure, as had once occurred in his own person and often in sailors visiting tropical coasts.

Dr. R. C. Newton had little doubt that the potted plants were the cause of the malarial infection as mentioned in the paper. He could give some experience which would seem to confirm that view. He had a friend who was a florist, and while generally in good health he had to guard against exposure on account of taking "colds," which he could cure by quinine. The question of atmospheric temperature in relation to malaria required further study. Around New York malaria was most common during seasons when the diurnal variation in the temperature was greatest; when there were warm days and cool nights. There were not wanting microscopists who regarded the plasmodium as the consequence, not the cause of malaria. Nor was he convinced that infection could not take through drinking-water.

Dr. J. W. Brannan had not seen in literature potted plants referred to in connection with the etiology of malaria. It might be that there was more malaria in New York City than some doctors were disposed to admit, and in potted plants might be an explanation.

Dr. R. G. Freeborn said there was a good deal of malaria which originated in New York City. It was almost invariably associated with enlargement of the spleen, and usually the malarial organism could be found. But in his opinion malaria and enlargement of the spleen existed not infrequently when ordinary examination failed to reveal the malarial organism. These statements were based on what he had seen at the Bellevue and Roosevelt dispensaries in children not from out of town.

Dr. T. S. Southworth had almost invariably been able to find a history of previous residence in the country in cases of malaria in children in this city. It was possible malaria might develop from plants in the room by reason of soil brought from New Jersey or Long Island.

Dr. Taylor said, in closing the discussion, that he had been surprised during a visit here this winter to learn that in the German Hospital of this city there were nearly equal numbers of patients with pneumonia and with malaria at a season of the year when pneumonia was supposed to be frequent and malaria infrequent. It appeared from an article in one of the journals that malaria had been frequent in Philadelphia the past winter, as well as in New York.

THE NEW HOSPITAL FOR INFECTIOUS DISEASES—THE CAVENDISH LECTURE—RELATION OF OVARIAN DISEASE TO PREGNANCY—ALCOHOLISM AND LEGISLATION—INCUBATORS—MEDICAL EDUCATION FOR WOMEN—VENEREAL DISEASE IN THE INDIAN ARMY—MERCER'S HOSPITAL DISPUTE.

London, July 16, 1897.

The Prince of Wales is doing a great work for the hospitals apart from the fund he is raising. On Monday, accompanied by the Princess, he opened the new Park Hospital, which has been built by the asylum's board for the further accommodation of cases of fever and diphtheria. For two years about eight hundred workmen have been engaged on these buildings, which are situated at Hither Green, near Lewisham, about six miles from London Bridge, in grounds of twenty acres. In 1896 there were 22,273 patients admitted into the board's hospitals for fever, but these were not sufficient for the metropolis, swollen to some five million inhabitants. Besides the small-pox accommodation, the board has nine hospitals for infectious cases, with forty-two hundred and fifty-four beds. The new building will add five hundred and forty-eight more. It is provided with everything of the most modern type. Another hospital, for five hundred and twenty beds, is in course of construction at Tooting, and it is proposed to build wards for seven hundred convalescents at Carshalton. When all this has been accomplished, there will be provision for six thousand patients at the disposal of London, which surely ought to suffice. The burden on the ratepayers is heavy, but it is felt that in the end they must benefit.

The Cavendish lecture this year was delivered by Sir John Williams, who devoted it to the consideration of the problems involved in cases of ovarian tumor in pregnancy. It has been asserted that pregnancy gives rise to these growths, but there seems no ground for the suggestion. If it were so, such tumors must surely be much more common. Taking the one thousand cases operated on by Sir Spencer Wells, and dividing them into groups according to age, the lecturer found, from twenty to twenty-five, ovarian tumors three times as frequent in the single as in the married, but after thirty-five the proportions were reversed. But then there is the great change in the relative numbers of the married and single with advancing age. At sixty-five single women have these tumors in the proportion of eight to one married, as far as the registrar-general's statistics show. By similar comparisons, Sir John Williams concluded that these tumors were less frequent in each successive pregnancy, and that there was no ground for Leopold's startling suggestion, based on two cases, that pregnancy is a cause of cancer of the ovary. It is surprising that such a notion should have been based on a couple of cases, one of Leopold's own and one of Spiegelberg; and that Wernich should have supported it on two others, one of his own and

one of Kursteiner. But strange things are "made in Germany." With regard to the conclusions from Sir S. Wells cases, it cannot be said that all the ovarian cases passed through that great surgeon's hands—a point which seems to me considerably to affect the statistics put forward, and, in fact, it is scarcely possible to furnish figures which statisticians would consider sufficient to build upon. The lecturer then considered the effect of such tumors on labor. The mortality, even when no great difficulty in delivery occurs, is "appalling"—and for explanation of this Sir John said we must look to injury done to the tumor itself and the parts adjacent, pelvic or abdominal. He saw but two ways of preventing such injury, either removal of the tumor during pregnancy or anticipation of labor by Cæsarean section. Not that all cases should thus be met, for small tumors in the abdomen or those which could be raised from the pelvis and retained in the abdomen do not suffer much injury during labor. With these exceptions he advised operation in all cases. Ovariotomy during the pregnancy had only half the mortality of cases left to natural labor. When this was impracticable, from adhesions or otherwise, he would have recourse to Cæsarean section.

Dr. Pitcairn, deputy medical officer of Holloway and Newgate prisons, read a paper on Monday on "Alcoholism and the Penal Laws of Europe and United States of America," before the Society for the Study of Inebriety. He awarded the distinction of having raised tippling to a fine art to Germany, where drinking has of late become, as it were, a part of the nationality of the people. He said most communities displayed the same attitude toward the public drunkard, who was regarded as a nuisance which it was attempted to abate by fines and imprisonment. The habitual drunkard has been too long ignored, though found everywhere. This he thought might be due to the worship of so-called liberty, and is perhaps a survival of the time when no disgrace was attached to intoxication. But during the last half-century there has grown up a conviction among psychologists that inebriety is a mental disorder requiring seclusion. The habitual drunkard has assumed a national instead of individual importance. Austria has recognized the necessity of grappling with the problems involved, and public opinion is ripe for reform of the laws of our own and other countries.

At the Victorian Era Exhibition there has been a private view of incubators. The "couveuse" so long adopted in France for rearing premature or sickly infants has been tried in some of our maternity hospitals with success, but the system has not been widely adopted here. In the exhibition mentioned, various improvements in the incubators are exemplified, especially as to the warming (by hot water) and ventilation. Portability has also been attained by the use of aluminium in their construction.

At the Woman's Congress on Education, held here this week, the idea of establishing a university for women alone was generally repudiated. Mrs. Garrett Anderson, M.D., was among the leaders, and gave some account of her own experience in the sixties in obtaining medical instruction. She delivered an address on medical education, in the course of which she said that with the six universities and three corporations now open to women, a new university for women only would not attract any woman to enter it. Meantime, the Women's School of Medicine is making great progress. The number of students increases, and the school is more than self-supporting.

The Indian government has taken steps to have a free hand in dealing with the prevention of venereal diseases among our soldiers. The viceroy and the commander-in-chief have both spoken forcibly in favor of the measures proposed. Nothing will be done that can be represented as encouraging vice, and this should disarm some of the opposition which is threatened. Already Mrs. Butler and Sir J. Stansfeld have raised their voices, and it is quite possible that their followers may give rise to considerable annoyance to the authorities, but they have no longer a chance of influencing the government, and public opinion seems to be against their views.

The Mercer's Hospital dispute has advanced a stage. Candidates have been found as I suggested — yes, twenty of them—and the governors have made their selection. But the end is not yet. Protests were handed in, and I am assured an appeal to law is impending. But that law is slow and uncertain. The lamentable fact remains that twenty men were ready to take the places of the dismissed staff—and we talk of the prestige and the honor of the profession!

OUR VIENNA LETTER.

(From our Special Correspondent.)

PROF. KARL TOLDT, THE ANATOMIST, ELECTED RECTOR OF THE UNIVERSITY—NEW SURGICAL AND GYNÆCOLOGICAL WARDS FOR THE VIENNA GENERAL HOSPITAL—CARBONIC-ACID BATHS FOR HEART DISEASE IN VIENNA—THE MENINGOCOCCUS INTRACELLULARIS AND EPIDEMIC SPINAL MENINGITIS—CANCER OF THE SINUS PYRIFORMES AND SO-CALLED BRANCHIOGENIC CANCER.

VIENNA, July , 1897.

PROF. KARL TOLDT, professor of anatomy, has just been elected rector magnificus of the University of Vienna for the scholastic year 1897-98. The tenure of office is but a year, and there is usually a rotation in the selection of candidates from the different faculties that constitute the university. Professor Toldt succeeds Professor Reinisch, a jurist.

It has at last been definitely decided that part of the old Vienna General Hospital must go. The increased traffic, with the incident noise and dust at the corner of Alserstrasse and Spitalgasse, made the wards here almost uninhabitable for patients. Since the advent of the electric tramway this state of affairs has been much worse. The line is one of the most travelled in Vienna, and is becoming more so. Its cars have had to be increased in number, and this will constitute more and more of an annoyance as time goes on. The old wards in the hospital have become a constant source of complaint, especially for the surgeons and gynæcologists. Aseptic surgery and aseptic post-operative courses are extremely difficult to secure with the limited facilities in the thoroughly old-fashioned hospital building. A series of wards on the pavilion plan are to be erected on the grounds of the Lower Austrian National Insane Asylum on Lazareth Gasse, which are to provide quarters for some eighteen hundred surgical and gynæcological patients; while the buildings at the corner of Alserstrasse and Spitalgasse are to be replaced by a large apartment house. Such is the ministerial decision, but as to when the plan will be accomplished, with the proverbial slowness of the Austrian government, especially when merely scientific matters are concerned, it is extremely hard to say.

For more than a year now series of observations have been made in two of the divisions of the hospital with carbonic-acid baths in the treatment of heart disease. The Schott or Beneke treatment has attracted a good deal of attention in America, too, so that the Vienna opinion of it will be of interest. They are not so enthusiastic over its success here as Schott himself is at Nauheim. It is not a novelty in therapeutics, however, to find that others do not meet with the same success in the use of a remedy as its originator.

Of course, here as everywhere else, except where there are abundant natural carbonic-acid springs, one labors under the disadvantage of having to employ artificial solutions of carbonic acid. Despite this, it has been found that in certain cases of heart disease, utterly intractable by the ordinary methods and remedies, the carbonic-acid bath is of great benefit. It has been found, too, that when the ordinary heart tonics fail to produce an amelioration of symptoms or are badly borne when employed only in conjunction with rest in bed, they regain their usual therapeutic effect after a course of carbonic-acid bathing. When used alone or in conjunction with the Swedish movements and absolutely without drugs of any kind, the baths often give excellent results, better than could be hoped for with ordinary methods of treatment. There are certain cases, however, in which they do not seem to produce the slightest effect. There are others in which, apart from aneurism or arterio-sclerosis, which are considered here absolute contraindications, they produce unfavorable effects. They increase cardiac arrhythmia, and sometimes occasion symptoms of collapse. It seems impossible to tell beforehand the cases in which these unfavorable effects will follow, as they are due to personal idiosyncrasy. On the whole, while the new treatment is a welcome adjuvant to the limited circle of cardiac therapeutic measures, it is by no means a universal panacea for heart disease, and needs care and judgment in its application.

A little epidemic of cerebro-spinal meningitis has been observed in Vienna in this last month. Several cases have turned up at the Franz Josef and Rudolf hospitals, and cases of meningitis occurring without easily recognizable etiology are suspected. For purposes of disinfection and necessary burial precautions, the post-mortem diagnosis is important, and that they make here with what is considered ample assurance from the bacteriological examination of the purulent exudate. The finding of the intracellular meningococcus decides the question in favor of epidemic cerebro-spinal meningitis. Weichselbaum's discovery of this coccus, its constant occurrence, and the description of its peculiarities have been confirmed by a number of German observers, until now its specific pathogeneity is considered settled. In a recent autopsy, in a case in which the clinical diagnosis had been meningitis from otitis media, and in which the destructive process in the petrous bone was very slight, while the meningeal suppurative exudate was widespread over the base and in the cord, the anatomical differentiation was considered to be assured only when the bacteriological examination of the exudate gave negative results as regards the meningococcus and showed the presence in large numbers of other pus-producing micro-organisms.

A case of recurring squamous epithelial cancer of the cervical glands, in which the patient succumbed after two operations, proved of special interest on the autopsy table last week. The most careful laryngoscopic examination by one of Vienna's best-known laryngologists had failed to discover any suspicion of neoplasm in the larynx or its neighborhood. At the autopsy a small cancerous nodule was found deep down in the right sinus pyriformis. It was evidently invisible to the laryngoscope, and yet undoubtedly the original seat of the cancer, which had given metastases to the cervical glands. These squamous epithelial cancers of the cervical region are often spoken of as taking their origin from embryonal vestigia of the branchial clefts, but one is tempted to wonder how often the simpler explanation of their metastatic origin from small cancerous nodules of the pharynx and larynx would be the real one. Undoubtedly this is the case much more frequently than is supposed.

DO ABNORMALITIES TEND TO DIE OUT IN THE COURSE OF TRANSMISSION?

[illegible]

SIR: In Dr. Park's paper upon "The Problems Which Most Perplex the Surgeon," published in the MEDICAL RECORD of July 3d, I find the following paragraph (page 3): "If cancer is transmissible by heredity and is not an infection, it should tend to die out in the course of transmission, as do all abnormalities. Thus, out of three hundred marriages in which both husbands and wives were deaf and dumb, in only five per cent. of the cases were the offspring similarly affected; while of three hundred and ten deaf-mutes married to those who could hear, the proportion of affected offspring amounted only to one in one hundred and thirty-five (Buxton)."

I feel a great deal of reluctance in challenging Dr. Park's statement; but my study of heredity, extending over a period of twenty years, leads me to the conclusion that congenital abnormalities are reproduced with very great certainty, and that it is extremely doubtful whether even the judicious mating of the sexes would "breed out" such pathological variations as epilepsy, hæmophilia, idiocy, and deaf-mutism. My opinion that congenitally abnormal persons should not marry, because they are likely to reproduce their abnormalities in their children, is supported by the views of such authorities as the late Oliver Wendell Holmes, the late Benjamin Richardson, Paget, Clouston, and Maudsley. It is most unfortunate that a physician of Dr. Park's eminence should teach that "all abnormalities tend to die out in the course of transmission," since it will encourage the physically deformed and the mentally incapable to marry without fear of the consequences.

Has Dr. Park proved that deaf-mutism "tends to die out in the course of transmission"? I trow not. Mr. Buxton (David Buxton, of Liverpool) is his authority, not mine, and the following quotation was addressed to the British Association in 1889 by Sir William Turner, who produced a mass of evidence, which he asserted "proves that it (deaf-mutism) is often hereditarily transmitted": "Mr. Buxton, who has paid great attention to this subject, refers to several families where the deaf-mutism has been transmitted through three successive generations, though in some instances the affection passes over one generation, to reappear in the next. He also relates a case of a family of sixteen persons, eight of whom were born deaf and dumb, and one, at least, of the members of which transmitted the affection to his descendants as far as the third generation" (*Liverpool Medico-Chirurgical Journal*, July, 1857: January, 1859).

But Mr. Buxton's evidence possesses a limited value, because he ignores the "metamorphoses" of heredity, and he pays very little attention to atavism. Moreover, he does not appear to have carefully distinguished between congenital and acquired deaf-mutism. The latter form of the disorder consists chiefly of instances in which deafness has followed some injury to the auditory apparatus before or shortly after the power of speech had been attained. This class (perhaps forty per cent. of all deaf-mutes) is large enough to influence statistics, and its existence partially explains the figures quoted by Dr. Park. Acquired deaf-mutism is, of course, no more hereditary than accidental blindness.

Every form of degeneration is liable to be transmuted in the course of generations. What is passed on from parent to offspring is a depraved constitution, which may manifest itself in half a dozen different diseases, such as hysteria, imbecility, idiocy, etc. Moreau (of Tours), in his "Psychologie Morbide," says: "It shows an incorrect conception of the law of hered-

ity to look for a return of identical phenomena in each new generation." Morel ("Traité des Dégénérescences") writes: "We do not mean exclusively by heredity the very complaint of the parents transmitted to the children, with the identical symptoms, both physical and moral, observed in the progenitors. By the term heredity we understand the transmission of organic dispositions from parents to children." My quotation from Mr. Buxton shows that he knew of this phenomenon as a factor in the heredity of deaf-mutism, although Dr. Park's quotation seems to prove that he underestimated its statistical value.

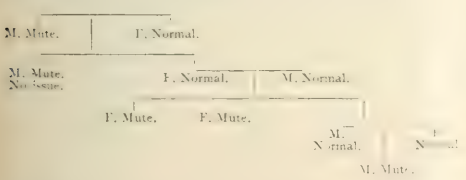
Ribot, in his work upon "Heredity" (page 42), writes: "We would remark that the returns of the Deaf and Dumb Institution of London, from its foundation to the present time (1875), are conclusive in favor of heredity." (Then follow statistics.) "The deaf-muteness of ascendants may, in their descendants, be transformed into an infirmity of some other description, such as obtuseness of the mental faculties or even idiocy. Of this the distinguished anatomist Menckel gives many instances."

Dr. Clouston, in "The Neuroses of Development," says: "Ordinary deaf-mutism is closely allied to idiocy, and is one of the hereditary neuroses. To me it is a physiological sin that marriages between such persons should be legal."

Congenital deaf-mutism is not mere inability to hear; if it were, I should not trouble you with this letter. It is a constitutional affection showing a markedly degenerate state, and is a sign that the family in which it is present is on the road to decay.

According to Prof. Graham Bell, idiocy is forty-three times as common, and blindness fourteen and one-half times as common, among deaf-mutes as among the general population. I assume that he means congenital blindness. I am sure that Dr. Park will agree with me that an idiot parent has a decided tendency to beget idiot children, however "normal," as it is called, the second parent may be. Professor Bell, a few years ago, wrote that "philanthropy is doing everything possible to encourage marriage among deaf-mutes. Unless this system is changed, we shall certainly have a deaf variety of the human race." Of this I see no danger, for, while we are increasing the supply of idiots, of lunatics, of deaf-mutes, of the deformed, *et hoc genus omne*, the tendency is for degenerated families to become sterile and consequently extinct.

The marriage of a deaf-mute with a so-called "normal" person is said to be unproductive of deaf-mutism in the next generation. "Normal" in this instance appears to mean that the individual can speak and can hear. I have no complete statistics of the results of this connubial combination, but I have sufficient evidence to lead me to suppose that it is productive of abnormality, not necessarily deaf-mutism, of course. The following case, a typical case of atavism, is vouched for by the Scotch Lunacy Commission:



With great respect, I submit that Dr. Park is mistaken in thinking that "all abnormalities tend to die out in the course of transmission." Upon the other hand, I feel sure that many pathological variations, when congenital, have a decided tendency to reappear in the next or some future generation. I believe I can demonstrate by irrefutable evidence that idiocy, insanity (not apparent till after puberty), epilepsy, the gouty diathesis, hæmophilia, color blindness, and the tuberculous diathesis—most of them signs of racial deterioration—are almost invariably transmitted.

LAWRENCE IRWELL, M.A., B.C.L.

[illegible] West [illegible] Street, Buffalo, N. Y.,
July 12, 1897.

THE TREATMENT OF TYPHOID FEVER.

To the Editor of the Medical Record.

SIR: In the issue of the MEDICAL RECORD for July 3d is an abstract of a paper in which my name was freely used—and also a synopsis of some remarks of my own, which in one respect does me too much and in another too little justice. Will you therefore accord me space to correct an erroneous impression which, in the MEDICAL RECORD, will have too large a circulation to be passed uncriticised?

Before remarking upon Dr. Upshur's allusions to "The Woodbridge Method" it is proper to say that he has my most hearty thanks for the polite and apparently sincere compliments he pays me, but when he characterizes the verdict rendered upon the clinical reports on the abortive treatment of typhoid fever as "erroneous conclusions drawn from cases of mistaken diagnosis," he is disparaging the achievements and discrediting the statements of a very large and very respectable class of American physicians, whose statements upon any medical question are quite as valuable as his own, and upon this subject much more so, since their remarks are the rehearsal of facts and the expressions of opinions that have been founded upon actual experience at the bedside, while his own can be fully characterized in no other way than as the liberal expressions of erroneous conclusions, the result of faulty reasoning from false premises.

Because Dr. Upshur does not understand the abortive treatment of typhoid fever, and because the exhibition of certain remedies produces results which he cannot believe to be possible, "unless the day of miracles had returned," he attempts to discredit it on the theory that "it had not been supported by the results"—a theory that can be sustained only on the assumption that the many hundreds of physicians who have aborted typhoid fever and have reported 8,434 cases treated, with 150 deaths (death rate of 1.88 per cent.), have made errors of diagnosis. Most of these deaths occurred in cases in which the treatment was instituted late in the course of the disease, or when the method was never properly applied, and yet all are included to silence all suspicion that the statistics have been "doctored," though they unjustly swell the death rate.

It is but just to Dr. Upshur to say that when he read his paper he was not aware of the enormous proportions that these statistics are assuming, but if he had read my book he would probably have found enough there to prevent him from putting himself in the dilemma from which he will find it difficult to extricate himself.

Let us examine the data contained in my paper read before the Ohio State Medical Society, which consisted almost entirely of brief quotations from the letters of hundreds of physicians from all parts of the country, from all walks of professional life, from the ablest professors, from physicians who were or who had been at the head of some of the largest hospitals in the United States, from the equally competent private practitioner—all of whom had used this method so successfully that many declared their convictions that death is a wholly unnecessary consequence of typhoid fever. Many whose ability to make correct diagnoses or to draw exact conclusions no man would

dare to question, said in most positive language that this method of treatment "aborts typhoid fever." Nearly all spoke in highest commendation of it. So far as I know, it has been adversely criticised by only twelve physicians who spoke from bedside, and some of these from an experience limited to the treatment of one, two, or three cases each.

This report dealt with the data of 5,449 cases of typhoid fever treated with 105 deaths (every death of which I had any knowledge)—a death rate of 1.92 per cent., and an average duration of illness in the 3,129 cases in which it was given of 12.7. These reports were accompanied by a large number of clinical charts or histories, and present conclusive evidence that they were the outgrowth of the most patient and painstaking observations, in which every precaution had been taken to avoid errors of diagnosis or judgment, and they show that the conclusions were justified by the results.

This paper was read on May 21, 1897, and since that day I have received more than three hundred letters containing the reports of 2,985 cases treated, with 54 deaths (a death rate of 1.80 per cent., which slightly reduces the death rate from that of the previous report), making the record stand now at 8,434 cases treated, with 159 deaths, or a death rate of 1.88 per cent., and an average duration of illness in the 5,372 cases in which it was given of 12.9 days.

Besides the bare statistics, the almost universal verdict of this host of observers is to the effect that the treatment greatly lessens the severity of the disease, causing it to run a mild course to quick recovery. Delirium or tympanites rarely develops after the treatment is instituted, and if present it generally quickly disappears, the tongue remains moist, the temperature runs lower or quickly drops to nearly or quite normal, and the "typhoid state" is unknown.

These results have been reported in thousands of cases in which the treatment was instituted after there could be no doubt as to the diagnosis, and it is to be regretted that Dr. Upshur has had the temerity to insult this great host of careful, scientific, self-sacrificing observers, and through them the whole medical profession, by stating that "the originator of the method must have drawn erroneous conclusions from cases of mistaken diagnosis."

The correction of the report of my own remarks may be very brief indeed. "He had never said a harsh thing about any member of the medical profession." This sounds well and I would it could stand unchallenged, but when I first declared that typhoid fever could be aborted the announcement was met by such sharp criticism, sometimes degenerating into personal abuse, that it would have required a much better temper than I possess to have enabled me to withhold all acrimonious retorts. The above quotation requires to complete it the qualification—until called forth and justified by the sharp criticism of a principle which cannot be successfully attacked. I was in a very apologetic mood when I made these remarks, which was due to the cordial reception which had been accorded me when I least expected it, and to the courteous and friendly letters which were then and are still coming from physicians who have used the method I have advised for the abortive treatment of typhoid fever and commend it.

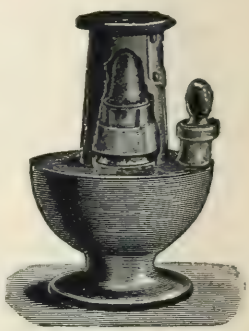
JOHN ELIOT WOODBRIDGE, M.D.
1257 PROSPECT STREET, CLEVELAND, OHIO.

The Austrian Universities.—The number of students at the Austrian universities last semester was: Vienna, 6,104; Gratz, 1,667; Prague, 1,391 German, 2,787 Bohemian; Innsbruck, 1,004; Lemberg, 1,556; Krakau, 1,296; Czernowitz, 391. Of the total number, 4,728 were medical students.

New Instruments.

A FORMALDEHYDE GENERATOR.

THE investigations of the last few years have shown that formaldehyde vapor is a most powerful germicide and antiseptic, exceeding in promptness and efficacy most of the disinfectants usually employed. In solution it is likewise a powerful antiseptic, and is now largely used for preserving anatomical specimens. What makes it so valuable as an air or room disinfectant is its lack of chemical action upon metals, colored fabrics, etc. A room may practically be saturated with it, and no metallic surfaces, bronzes, paintings, dresses, or the like will be injured by the vapor.



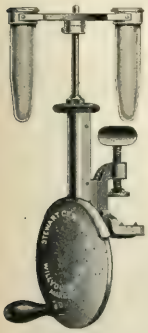
If chlorine or sulphurous-acid gas are used, articles which are liable to be injured must either be removed from the room, or coated with varnish or wax, or some other protective. In either case there is a chance that some of the germs intended to be destroyed are removed from the sphere of action of the disinfectant. With formaldehyde vapor this is different. Everything may be left in the room, uncovered or unprotected, and the apparatus set going. The accompanying illustration represents a generator for the diffusion of formaldehyde vapor. It is produced in this apparatus by a very simple application of the best method now available, viz., the passage of a mixture of the vapor of wood alcohol and atmospheric air through platinum gauze in a state of red heat, thus causing flameless combustion of the same. In less than one minute the process can be brought into operation and it will continue without further effort as long as the supply of wood alcohol lasts. The apparatus is manufactured by John Reynders & Co., of this city.

A SIMPLE, CONVENIENT, AND EFFICIENT CENTRIFUGE.

BY A. H. STEWART, M.D.,
PHILADELPHIA, PA.

THE great value of the centrifuge as an efficient and speedy aid to diagnosis is now well recognized by all. Having had occasion during the past five years to make considerable use of the centrifugal method, I became early convinced that most of the instruments were unnecessarily complex. I therefore undertook the task of designing an instrument which should be at once adequate to the purpose, as well as strong, and at the same time simple in construction. In this work I have been aided greatly by the mechanical skill and ingenuity of Messrs. Willyoung & Co., of Philadelphia, whose facilities were very kindly placed at my disposal. In the accompanying figure is illustrated the instrument which I have designed. There is but one pair of gears, viz., that made up of the large circular bevel gear, to which the handle is affixed, and a smaller beveled pinion at the base of the main shaft. The bearings are of polished, hardened steel; that of the large gear is long and the gear wheel

itself is very stiff, so that no twisting or binding of the gears can take place. The main casting and the clamp casting are separate, so that should the latter break it may be easily replaced. As both are very strongly ribbed, however, no breakage is anticipated. The clamp has considerable area and is so designed that it is impossible for the instrument to twist loose when in use. The thumb nut is above instead of below, so that attaching or removing the instrument is easy. The urine receptacles are of the usual conical test-tube shape, held in the ordinary aluminium guards; they have a capacity of ten cubic centimetres and one of them is graduated in tenths of a cubic centimetre.



The supporting frame merely slips upon the shaft and engages with the ring by means of a steady pin; no bayonet catch or screw action is found necessary. A soft rubber ring acts as a buffer in case the tubes drop too suddenly. In practice, however, it is found that this ring is not really needed, as the tubes drop slowly and freely into the vertical without any tendency to swing inside and strike the frame. A metal guard covers the gears and shaft, and makes it impossible for fluid to be thrown into them.

Each turn of the handle gives twenty-three revolutions of the main shaft, so that a constant speed of from one thousand five hundred to two thousand five hundred revolutions is provided for; this lower limit here mentioned has been found amply sufficient for all urinary, water, and milk analyses.

252 North Twelfth Street.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending July 24, 1897:

	Cases.	Deaths.
Tuberculosis	180	97
Typhoid fever	13	9
Scarlet fever	83	6
Cerebro-spinal meningitis	2	4
Measles	148	5
Diphtheria	184	22
Laryngeal diphtheria (croup)	5	2
Chicken-pox	6	0
Small-pox	0	1

Study of the American Medicinal Flora.—The Pan-American Medical Congress, at its meeting held in the City of Mexico in November, 1896, took steps to institute a systematic study of the American medicinal flora, through the medium of a general commission and of special subcommissions, the latter to be organized in the several countries. The subcommission for the United States has been formed, and consists of Dr. Valery Havard, U. S. A., chairman; Mr. Frederick V. Coville, botanist of the United States department of agriculture; Dr. C. F. Millspaugh, curator of the botanical department of the Field Columbian Museum, Chicago; Dr. Charles Mohr, State botanist of Alabama; Dr. W. P. Wilson, director of the Philadelphia Commercial Museums; and Prof. H. H. Rusby, of the New York College of Pharmacy. This subcommission solicits information concerning the medicinal plants of the United States from every one in a position to accord it. The principal points of study are as follows: 1. Local names. 2. Local uses, together with historical facts. 3. Geographical distribution and degree of abundance in the wild state. 4. Is the plant collected for market, and if so: (*a*) At what season of the year? (*b*) To how great an extent? (*c*) How prepared for market? (*d*) What is the effect of such collection upon the wild supply? (*e*) What price does it bring? (*f*) Is the industry profitable? 5. Is the plant, or has it ever been, cultivated? If so give all information on the subject, particularly as to whether such supplies are of superior quality and whether the industry has proved profitable. 6. If not cultivated, present facts concerning the life history of the plant which might aid in determining methods of cultivation. 7. Is the drug subjected to substitution or adulteration? If so give information as to the plants used for this purpose. While it is not expected that many persons will be able to contribute information on all these points concerning any plant, it is hoped that a large number of persons will be willing to communicate such partial knowledge as they possess. It is not the important or standard drugs alone concerning which information is sought. The subcommission desires to compile a complete list of the plants which have been used medicinally, however trivial such use may be. It also desires to collect all obtainable information — historical, scientific, and economic — concerning our native and naturalized plants of this class, and to this end invites the cooperation of all persons interested. Poisonous plants of all kinds come within the scope of the inquiry, whether producing dangerous symptoms in man, or simply skin inflammation, or, as "loco-weeds," being deleterious to horses, cattle, and sheep. In this respect, the general reputation of a plant is not so much desired as the particulars of cases of poisoning actually seen or heard from reliable observers. It is believed that much interesting knowledge can be obtained from Indians, Mexicans, and halfbreeds, and that consequently Indian agencies and reservations are particularly favorable fields for investigation. Such knowledge will be most acceptable when based upon known facts or experiments. In order to assist in the study of the habits, properties, and uses of medicinal plants, the subcommission undertakes to furnish the name of any plant specimen received, together with any desired information available. Owing to the diversity in the common names of many plants, it will be necessary for reports, when not furnished by botanists or others qualified to state the botanical names with certainty, to accompany the same with some specimen of the plant sufficient for its identification. While the subcommission will endeavor to determine the plant from any portion of it which may be sent, it should be appreciated that the labor of identification is very greatly decreased, and its usefulness increased, by the possession of complete material—that is, leaf, flower, and fruit, and in the case of small plants, the underground portion also. It is best to dry such specimens thoroughly, in a flat condition under pressure, before mailing. While any convenient means for accomplishing this result may be employed, the following procedure is recommended: Select a flowering or fruiting branch, as the case may be, which when pressed shall not exceed sixteen inches in length by ten inches in width. If the plant be an herb two or three feet high, it may be doubled to bring it within these measurements. If it possess root leaves, some of these should be included. Lay the specimen flat in a fold of newspaper, and place this in a pile of newspapers, carpet felting, or some other form of paper which readily absorbs moisture, and place the pile in a dry place under a pressure of about twenty or thirty

pounds, sufficient to keep the leaves from wrinkling as they dry. If several specimens are pressed at the same time, each is to be separated from the others by three or four folded newspapers or an equivalent in other kinds of paper. In from twelve to twenty-four hours these papers will be found saturated with the absorbed moisture, and the fold containing the specimen should be transferred to dry ones. This change should be repeated for from two to five days, according to the state of the weather, the place where the drying is done, the fleshiness of the specimens, etc. The best way to secure the required pressure is by means of a pair of strong straps, though weights will do. The best place for drying is beside a hot kitchen range. When dry the specimens should be mailed between cardboards or some other light but stiff materials which will not bend in transit. It is a most important matter that the name and address of the sender should be attached to the package, and that the specimens, if more than one, should be numbered, the sender retaining also specimens bearing the same number, to facilitate any correspondence which may follow. The subcommission requests that, so far as practicable, all plants sent be represented by at least four specimens. All packages and correspondence should be addressed to the Smithsonian Institution, Washington, D. C., and marked on the outside, "Medicinal Plants, for the United States National Museum." Franks which will carry specimens, when of suitable size, together with descriptions and notes, free of postage through the mails, will be forwarded upon application. Should an object be too large for transmission by mail, the sender is requested, before shipping it, to notify the institution, in order that a proper authorization for its shipment may be made out.

The Founder of Guy's Hospital.—Guy, the founder of Guy's Hospital in London, was as parsimonious in private life as he was munificent in public. A good story illustrative of this is told of him in connection with John Hopkins, one of his contemporaries who was nicknamed Vulture Hopkins, on account of his rapacious mode of acquiring his immense wealth. On one occasion he paid a visit to Guy, who, on Hopkins entering his room, lighted a farthing candle. Hopkins, on being asked the reason of his visit, said: "I have been told that you, sir, are better versed in the prudent and necessary art of saving than any man living, and I therefore wait on you for a lesson in frugality. I have always regarded myself as an adept in this matter, but I am told you excel me." "Oh," replied Guy, "if that is all you came to talk about, we can discuss the matter in the dark;" and thereupon he blew out the candle. Struck with this example of economy, Hopkins acknowledged that he had met his superior in thrift.

Treatment of the Wounded in the Græco-Turkish War.—Dr. Zavitziano sends to Surgeon-General Wyman, of the Marine Hospital service, a distressing picture of incompetence and cowardice displayed by the surgeons of the Greek army and Red Cross Society. It is interesting as well as sad, he writes, to note that the Greeks, who as individuals are so skilful and capable of doing so many good things, when assembled and forming a government are incapable of doing anything. The Greek Red Cross, for instance, was not of any assistance, and nearly the same may be said of the sanitary service of the Greek army, for the wounded, as well as the refugees, have rather suffered from them. The wounded and the refugees have been attended with efficiency by private physicians, by private persons, and by rich Greeks, who have substituted what the Greek government, the Greek Red Cross, and the sanitary service of the army have not been able to do. Before the beginning of the war the Greek Red Cross had established five hospitals for wounded, one at each of the following places: Volo, Larissa, Tyrnavo, Carvassara, and Arta. Each of these hospitals was fitted for fifty beds. The hospital at Larissa was complete, and it was made the headquarters of the Red Cross. All the Red Cross material had been accumulated there, and according to the lowest calculation there was more than $20,000 worth of material included in the armamentarium. The wounded of the Greek army have been deprived of this material, as the hospitals of Larissa and Tyrnavo were abandoned to the Turks by the physicians, who, Dr. Zavitziano says, had no sense of their duty or they had forgotten it at that moment. The sole excuse they could offer was that the Turkish army had fired on the Red Cross hospital at Arta. As a consequence of the above-mentioned cowardly action of the physicians of the Red Cross, as well as of the army surgeons, the poor wounded were left without any aid; but, thanks to civilian physicians, everything has been re-established, and the wounded, as well as the refugees, have been attended to and helped. Greek physicians from abroad have arrived in Greece in order to serve their country, and, thanks to them, the wounded have been attended. A Greek lady, whose example has been followed by others, established a floating hospital on a steamship, by which the wounded were carried from the seaports, near the battlefields, to Athens, Piræus, Khalcis, Patras, Cephalonia, and Corfu, where well-organized hospitals exist. All the wounded, except those whose condition did not allow them to be carried, and they are no more than two hundred, have been transported to the above-mentioned cities, where the populace does all that it is possible to do in order to relieve their sufferings. There are in Athens four large hospitals and five or six public or private buildings and houses transformed into hospitals. The latter are maintained by private contribution. There are numerous schools as well as large private houses on which a Red Cross flag is hoisted, where the victims of the war, or rather of the Greek government, are attended. It has been observed that the wounded Turks are constantly visited by the German minister, who visits only them.

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service during the week ended July 24, 1897:

SMALL-POX UNITED STATES.

		Cases.	Deaths.
Toledo, Ohio	June 1st to 31st	..	1
Brooklyn, N. Y.	July 10th to 17th	1	
Memphis, Tenn	July 10th to 17th	1	
New York, N. Y.	July 10th to 17th	..	1
Pensacola, Fla	July 3d to 11th	1 case Variloid.	

SMALL-POX FOREIGN.

Calcutta, India	May 29th to June 4th	..	2
Glasgow, Scotland	June 26th to July 3d	1	
Hong-Kong, China	May 25th to June 12th	..	1
Madras, India	May 28th to June 11th	..	5
Madrid, Spain	June 23d to 30th	..	3
Manaos, Brazil	June 12th to 26th	103	12
Sagua la Grande, Cuba	July 3d to 10th	124	4
Moscow, Russia	June 16th to 26th	1	1
Nagasaki, Japan	June 24th to 25th	8	1
Odessa, Russia	June 26th to July 3	2

IS PAIN A VALUABLE SIGN IN THE DIAGNOSIS OF CANCER OF THE BREAST?

BY CHARLES N. DOWD, M.D.,

NEW YORK,

ATTENDING SURGEON TO THE NEW YORK CANCER HOSPITAL.

THERE is still a prevalent belief that cancer of the breast is painful in all its stages. Physicians as well as patients continually express surprise when such cancers have reached an advanced stage without pain; and even in one of our most recent systems of surgery the article on mammary tumors conveys the impression that we may expect a woman to be suffering pain if she has a cancer of the breast. This belief is probably due to the failure to discriminate between the early and late symptoms of the disease. In the late stages, after surrounding structures are pressed upon or ulceration exists, more or less pain is generally felt; but in the early stages it is seldom present.

In order to study the relationship between pain and beginning cancer, and to draw attention anew to the fact that tumors should not be considered bland because they are painless, I have examined the histories of the patients who have been treated in the New York Cancer Hospital for mammary cancer since January, 1889. In the history blanks there is a space for recording the presence or absence of pain and any other pertinent facts concerning this symptom, and this has usually been filled in with care.

The total number of cases was three hundred and thirty-one, in most of them the disease was far advanced.

In sixty-three cases pain was denied in any stage of the disease.

In fifty-six cases pain was not mentioned.

In one hundred and ninety cases pain came in the late stages of the disease after the surrounding structures were pressed upon.

In twenty cases pain was present in the early stages of the disease.

Hence in only 6.04 per cent. of the cases is there a record of pain at the time when the diagnosis should have been made in order to secure the best results from operation. Even in these few cases the pain was of such a character as to give little alarm to the patients.

In five instances it followed bruises.

In one instance it was caused by what was supposed to be a boil.

In seven there were only slight shooting or aching pains, which hardly attracted attention at the time.

In six there were severe pains at the beginning, which intermitted more or less afterward.

These six cases represented the greatest amount of early pain which was recorded in the entire series of three hundred and thirty-one patients. Yet the average duration of their disease had been twenty months when they were admitted to the hospital—an indication that the pain had not been very troublesome, else it would have been relieved sooner. People will not endure severe pain for twenty months when it can be so easily relieved.

Even in the later stages of the disease pain was not a prominent symptom. Many of the patients who denied pain at any time had advanced growths; and in the group of one hundred and ninety patients who had pain late in the disease there was seldom much suffering from this cause. The records usually say: "Occasional shooting pains," or "Dull pain from time to time." I have seen severe pain accompanying cancer of the breast only when there was abscess or phlegmon in addition to the cancer, or when axillary pressure caused œdema of the arm.

The explanation of this absence of pain is to be found in the peculiar nature of the growth. As the cancer grows it replaces the neighboring normal structures; it does not distend them, as acute exudative inflammation does. Cancerous, tuberculous, and syphilitic inflammation are similar in this respect, and all three usually progress without much pain; while inflammation in which there is an exudation of fluid under high pressure is very painful.

Abscess of the breast, acute articular rheumatism, and a "felon" illustrate this point, when contrasted with beginning cancer of the breast, tuberculous joint disease, and syphilitic dactylitis. The first three are very painful; the last three seldom give pain, excepting when motion or trauma brings pressure on nerve endings which are still sensitive.

Growing fibrous tumors in the breast are more likely to give pain than is growing cancer. There were thirty-seven such treated at the hospital during the time mentioned, and nineteen are recorded as painful in the early stages, the pain being usually of a sharp shooting character, frequently most severe at or about menstruation. This, indicates that, if a small nodule is painful, it is more likely to be fibrous than cancerous.

From a practical standpoint this freedom from pain in beginning cancer is most unfortunate, as people are not apt to seek medical or surgical advice about anything which seems so unimportant. We may well believe that in many instances they do not themselves know of their malady until it has existed for some time. We are, however, doing our best in the matter if we endeavor to call general attention to the real condition.

Vaginal Cystocele.—The operation for this condition, as performed by Dr. De Marsi, is described in the *Gazzetta degli Ospedali*, March, 1897, as follows: He first makes a longitudinal median incision through the mucous and submucous tissues of the anterior vaginal wall, extending from the fornix to the suburethral tuberculum, if necessary, and then two small transverse incisions, perpendicular to the first incision, at each end of it, and raises the square side flaps thus formed. He next sutures the two attached edges of these square side flaps together, and reduces the prolapsus, completing the operation by suturing the free edges of the flaps. By this means a solid foundation for the vaginal wall is secured and threatening prolapsus uteri averted. The same process could be applied to rectocele, with slight variations.

PERSONAL EXPERIENCES IN LAPAROTOMY.

BY MARY A. DIXON JONES, M.D.

My cases come within the period 1879 to 1889. I will now give my work, all that I have attempted or performed. My first case was that of a patient brought me from Maine by her husband; the tubes and ovaries were wrapped in a mass of disease. At the time it occurred to me that as these organs were incurable, and could be of no possible utility, they should be removed. This was the thought that forced itself upon me. I had not then heard of "Tait's operation" or of "oöphorectomy." So entirely engrossed had I been with my own practice that my medical journals were unopened, nor did I have time to think of the advance of surgery in any direction; but this procedure seemed so right, so self-evident, that I should have proposed it, had not attention, as I learned, been already called to it.

I invited Prof. B. F. Dawson to see this patient with me, and on the day of the operation, imagining she might have a better chance if Professor Dawson performed it, I invited him to do so, and he kindly complied. So now, when it comes to the arithmetic of statistics, I cannot put this, my first patient, on my list. Dr. Dawson reported the case to the New York Obstetrical Society[1] and before his class in the New York Post-Graduate School, presenting the specimens on each occasion.

My first laparotomy was performed October 18, 1884. The patient was brought to me from Connecticut by her parents, in June, 1884. She had been an invalid seven or more years—once she did not leave her bed for a period of eighteen months. After examination I informed the parents that I did not believe any amount of treatment would restore the organs to health, and that nothing would cure or relieve the patient but the removal of the hopelessly diseased structures. Still I advised treatment to see if an operation could not be avoided, or at least to get the patient in better condition. Careful and continuous treatment I gave this patient for four months; she may have improved somewhat in general condition, but I believe the organs were growing worse all the time, and in my report of the case I said the operation should have been performed years before; and now I say of her, as I can say of many or most of the patients in this list, that if she had not had the operation, she would long since have been in her grave.

My second case of laparotomy was for bleeding myoma. The patient came from Maine to see me, March, 1885, and on May 19th I removed the uterine appendages. She made a most happy recovery. Subsequently with the microscope I studied carefully the tubes and ovaries of this patient, to see what pathological changes might have taken place. In the tubes I found chronic interstitial salpingitis, and the ovaries were in acute and subacute inflammation. It was in the ovaries of this patient that I for the second time recognized diseased ova. In other cases of removal of the uterine appendages for myoma, I have made a thorough study of the pathological conditions of the appendages, and in every instance have found in them profound and chronic disease; so that I remarked, in an article in the *New York Medical Journal* of September 1, 1888, that in cases of fibroid of the uterus the tubes and ovaries were always so diseased that on that account their removal was demanded; and that probably this disease of the appendages caused the development of the myoma. Of this I have, from subsequent research, become more convinced.

[1] May 15, 1885. American Journal of Obstetrics, 1885, p. 1,192.

My third case of laparotomy was also for a helpless invalid, who for fifteen years had been suffering and had been refused admission into two hospitals, having been informed at one institution that "the hospital did not receive incurables." I admitted the patient into my private hospital. She made a most excellent recovery.

Every patient in the following list of laparotomies has an interesting history. The cases are from my private practice, from two dispensary clinics, and six patients were sent me by physicians. One of the dispensaries referred to had from eight to twenty patients daily, the other had from twenty to forty-five; and, what is a singular circumstance, in the first dispensary I seldom found a case of "pus tubes," while in the second I had them every day, and have counted in one clinic as many as seventeen patients with this disease. We could not possibly operate on all who needed operation, so for my cases I selected the patients who seemed physically to be in the most serious or dangerous conditions; and thus it transpired that I, without understanding the disease, had many cases of endothelioma of the ovary—a disease which I was first to recognize, and which at the time I submitted to the kindly consideration of the medical profession. Few diseases make such serious inroads upon the system, cause more pain, or have more pronounced symptoms. There are marked emaciation and, in advanced cases, almost the cadaveric hue of cancer or consumption, and a general cachexy of the system. The first patient in whom I recognized this disease was one on whom I had operated on June 25, 1885. Dr. Charles Heitzmann, in looking at the long protoplasmic masses of this growth, at first pronounced it "sarcoma," and subsequently said: "We shall have to term it either endothelioma or alveolar sarcoma."

The next case in which I found this disease was that of a patient on whom I operated for the removal of the uterine appendages, May 10, 1887 (Case No. 23). This patient was so emaciated, so cadaveric, that I at first thought she had phthisis, or, more likely, cancer of the liver. I presented the uterine appendages before the New York Pathological Society the same month, and, subsequently, microscopical slides of the growth. Also, Prof. Mitchell Prudden, then president of the society, at my request took a small section from each of the ovaries of this patient, and had them mounted in his laboratory. He wrote me it was "carcinoma," also sending a slide so labelled. I sent a microscopical slide of these ovaries, mounted by Dr. Louis Heitzmann, to Professor Waldeyer, of Berlin. He replied, October 18, 1887, that "the growth is carcinoma;" and certainly, in studying the minute anatomy of this growth I could readily believe it might be some form of cancer. I am still more impressed with this when I see the effects of the disease upon the system, as I said in an article in the *New York Medical Journal*, September, 1889: "When we look at this rapidly growing formation and the great masses of granules, the impression forces itself upon us that it may be malignant. Future investigation may prove it so. The cancer epithelia do not multiply more rapidly, or destroy the tissues more surely, or seem more threatening or monstrous in their appearance and growth."

While in this list I have included all my cases of laparotomy, whether for splenectomy, hysterectomy, or ovariotomy, yet most of the operations were for the removal of "diseased uterine appendages." Some eminent surgeons, as they have thought proper, have removed the uterine appendages for "ovaralgia," "dysmenorrhœa," and various nerve conditions; but I never could accept this idea. I have all the time maintained that whatever might be the symptoms, local or constitutional, the tubes and ovaries should not be re-

moved except for profound disease of the organs themselves, when they are incapable of being restored to health, and when their remaining becomes a positive injury to the system. I said in 1888,[1] and now repeat: "I have never operated on a case but I had full and substantial reasons to diagnose incurable disease of the appendages;" in the same article declaring: "I would not remove the uterine appendages for mental or neurotic diseases unless I believed the appendages were diseased," and the disease absolutely demanded their removal. I have even hesitated in some instances to remove the uterine appendages when they were profoundly diseased, and when there were indications even apparently necessitating an immediate operation. A patient, twenty-three years old, entered the Woman's Hospital, July 5, 1887. One ovary was enlarged to the size of a small orange and bound in on all sides by adhesions; the tubes gave evidence of pyosalpingitis. But this patient had had a child thirteen months before! If these organs are capable of these functions, why not leave them? Any one might have known that with conditions existing as they were in this woman it was impossible for conception to take place; but I wanted to give her the millionth part of a chance, so sincerely do I congratulate a woman who has children. The patient was in the hospital forty-six days and everything was done to improve her condition: she seemed in many respects much better and comparatively comfortable, so on the 20th of August I dismissed her from the hospital and sent her home. As soon as she commenced to be on her feet and go around, she realized that her sufferings were just the same, and just as intolerable. She returned to the hospital three days afterward, and again begged that the operation might be performed. In due time it was done. This is Case No. 33. The patient was in a dangerous condition, and should, when first in the hospital, have been operated upon without delay. Not only was there destructive disease of the tubes, but a blood cyst in the left ovary was in immediate danger of rupturing, with possibly fatal results. Besides, to show still more plainly how futile was the delay, every ovum in both of her ovaries was in helpless ruin.

Another patient to whom I tried in the same way to give the possibility of a chance—subsequent events proving it was quite as useless—entered the Woman's Hospital of Brooklyn, March 21, 1888. Hoping to save the tubes and ovaries, I gave her special local and constitutional treatment. She improved, and we dismissed her April 17, 1888. After returning home she realized that her trouble was still there, and of her own accord she returned to the hospital in four days, and again requested that the diseased organs be removed. This is Case No. 59. In this instance also I realized that it was not only a useless but a dangerous delay.

In September, 1888, Dr. B——, of Bridgeport, Conn., brought a young woman, twenty-six years old, married three years, and without children. In my report of this case, in the *Pittsburg Medical Review*,[2] October, 1889, I said: "It seemed so extremely sad for one so young and so lately married to be deprived of all chance of the sacred privilege of motherhood, that I suggested to Dr. B—— that the patient return home and have the cervix dilated and the anteflexion corrected, and thus give her, if possible, a chance." The patient at once objected to any delay, insisted upon immediate relief, and the physician added: "Treatment has been tried." This is Case No. 69. There was immediate demand for the operation. The pathological conditions showed that it should have been done without delay, even before the time the patient visited me.

In every case that I have operated on I have, in studying the pathological specimens removed, become more impressed that not only was there, in each instance, a necessity for the operation, but in each one it should have been done at an earlier period than it was performed. The great danger in these conditions is delay; and this delay is an injustice and a loss to the patient. As to delaying these operations for a possible conception, in every one of these patients, as was subsequently demonstrated, all capability of any physiological functions of the tubes and ovaries was destroyed by the existing disease; and in every one this complete destruction was still further emphasized by finding in the ovaries of each, as far as examined, only diseased and ruined ova.

In some, even of young women, I found complete destruction of these important structures, not one egg in either ovary; thus giving new proof of and new insight into what I said in 1886,[1] and repeated September 28, 1889:[2] "The disease that caused the suffering has also produced a profound sterility." After careful study into the pathology of every specimen I have removed, I again repeat, as was my impression on the first examination of the various patients, that not only was there a necessity for the operation, and that in each case the operation should have been done at an earlier period, but in every instance, as I told the patient, there was no capability or possibility of conception. My stereotyped expression, repeated to many, was: "With or without the operation, you can't have children." The operations were done to save life, and if possible to restore to health and active usefulness.

Of all the cases, there were of pyosalpingitis seventy-nine. Not only did the tubes contain pus, but their walls, as I afterward demonstrated, were more or less destroyed by suppurative inflammation. The ovaries were equally diseased. These all involved difficult and dangerous operations.

There were two operations for cystoma, or ovariotomy. Probably these were the least difficult of all the operations in the list; even the removal of a cystoma that contained over sixty pounds of fluid (Case No. 89) was in no way a difficult operation and was performed with great ease and celerity. Yet a writer uses this expression:[3] "I have long entertained the opinion that ovariotomy is the most difficult operation in the whole field of surgery." I must differ from the writer, for I have long maintained the belief that ovariotomy generally is one of the least difficult operations of abdominal surgery. Duncan says:[4] "It cannot be too strongly enforced that removal of the appendages for chronic disease is, in most cases, much more difficult than performing ovariotomy." Dr. G. Bantock says:[5] "Difficulties far exceeding those of nine out of ten of the ordinary run of ovariotomy." Sir Spencer Wells on the same occasion: "It is more difficult than ordinary ovariotomy." Dr. A. Martin, of Berlin: "The operation is not only difficult, but dangerous." Lawson Tait: "It is in almost all instances a difficult operation, sometimes one of exceeding difficulty." Dr. L. S. McMurtry[6] gives his testimony: "To remove pus tubes and adherent ovaries is among the most severe tasks of operative surgery." And Dr. Thomas Keith, nearly thirty years before, said: "There is no

mystery in ovariotomy; it is not a difficult operation."

But certainly there is often great difficulty, and mystery too, in leading out diseased uterine appendages from a complexity of dense adhesions. So difficult is this that Dr. Thomas Savage, of Birmingham, said[1] that in five of his forty cases he was unable to do anything beyond the simple abdominal section, on account of the strength and character of the adhesions; adding: "In others I was obliged to leave behind a part of one ovary at least." Dr. C. E. Penrose, in reporting eleven cases, remarked: "In one case I found it impossible to remove the left tube and ovary, they were so firmly adherent." A similar record has been made by many great surgeons.

In this list there was one case of cancer, No. 55, carcinoma on the floor of the pelvis,[2] and the cancerous material had infiltrated the tubes and ovaries. At the time of the operation, March 19, 1888, so convinced was I of the malignancy of the disease and the hopelessness of the case, that immediately I informed the husband that the patient probably would not live three days. But she did so well and made so good a recovery that I dismissed the idea of malignancy until the following December, when, in due course, studying the pathology of this specimen, I found that it was not only cancer, but cancer of the most malignant type. In the specimen there were really three forms of cancer—scirrhous, adenoid, and medullary.

Further, in studying this pathological specimen, it was seen for the first time and clearly demonstrated that the indifferent or medullary corpuscles were changing to large polyhedral epithelia, and forming cancer nests. This change of inflammatory corpuscles to cancer epithelia had never before, so far as I know, been observed or mentioned. It was a startling thought.

Also in this specimen there was revealed the interesting fact that the lymph vessels carry the cancer epithelia. This had long been supposed to be the case, but so far as I know had never before been verified or demonstrated. Under high powers of the microscope the lymph vessels were clearly seen to be largely dilated and carrying their burden of cancer epithelia. It was a revelation!—marvellous!—to see these vessels so crowded and so infinite in number!

Another fact to be noted: This patient had suffered for years with the continued distress and irritation of diseased uterine appendages. If, ten years previously, these organs—even then profoundly diseased—had been removed, the unfortunate woman might have been saved not only the infection of her system from the diseased tubes and ovaries, but the subsequent development of cancer.

Dermoid cysts, one case (No. 34). This was one of the most difficult and dangerous of the whole list of operations. The case was reported to and the specimens were presented before the New York Pathological Society, September 28, 1887. Dr. William Goodell said:[3] "In my experience dermoid cysts are very apt to have firm and extensive attachments, which make their removal far from easy." Dr. Thomas Keith reports a dermoid cyst;[4] so far as I could make out the conditions, they were very similar in every respect to those in my case—ovaries in each universally adherent. The operation performed by Dr. Keith lasted three and one-half hours, and the patient died thirty-six hours later. In my case of dermoid cyst the patient made a rapid recovery, and subsequently had good health.

The number of cases of abscesses of or connected with the ovaries was twenty-eight. Dr. Lawson Tait said: "In a majority of instances probably death occurs from the rupture of the abscess into the peritoneum." He reports[1] one case before the British Gynæcological Society, and says: "Operation extremely difficult, and hemorrhage severe."

Intraligamentous cysts, one case (No. 62). Dr. Goodell says:[2] "Intraligamentous cysts present grievous complications, which tax the pluck and skill of the operator to the utmost." Dr. Paul F. Mundé says:[3] "They are to me the most formidable tumors of the uterine appendages; three out of five deaths after laparotomy occurred in intraligamentous cysts." My patient (No. 62) made a rapid recovery.

Endothelioma, twenty-two cases. This is a more frequent and a more serious disease than many imagine, not only causing much suffering but being destructive to health. I believe an untold number of women have died from this disease or from the complications arising therefrom.

Of hæmatoma, the outcome of endothelioma, there are ten cases. Dr. Howard Kelly, before the Obstetrical Society of Philadelphia,[4] exhibited a specimen of hæmatoma of the ovary with adherent Fallopian tubes, remarking: "The hæmatoma is about the size and shape of a large Spanish chestnut. The indications for operative interference, after I had made my diagnosis, were greater than in the case of any large ovarian cyst I have ever seen, and the prospects and results of any form of palliation were futile. Almost the whole of this large ovary is filled with a bloody cyst." Dr. A. P. Dudley reported to the New York Pathological Society[5] a hæmatoma of the ovary, occupying nearly the entire organ, for which previous to its removal he had "for a year adopted every variety of general internal treatment, with external applications, but the woman was not in the least relieved." Dr. Boldt has reported a rupture of hæmatoma, or blood cyst, and states that but for immediate operation death would have ensued. Dr. R. H. Reed says:[6] "Early surgical relief is the only safe and reliable course of treatment." Dr. R. A. Murray reported a hæmatoma of both ovaries,[7] saying: "There was an extreme amount of adhesions, which rendered the operation most difficult, prolonging it three hours."

Gyromatous cysts, eight cases. Gyroma is another disease which I was first to recognize. These cysts have hard, firm walls, sometimes in waxy degeneration, or in intense inflammation, or again are being reduced to firm fibrous connective tissue—in any state necessarily compressing delicate nerve fibre, and giving rise to various neuroses and reflex irritations.[8] As I said in the *New York Medical Journal*, May 10, 1890: "The irritation of these hard, firm growths amid the delicate tissues of the ovary not only causes pain, but, if anything would produce cancer of the ovary, the continued irritation of these nodular masses would seem to be sufficient."

Blood cysts, also the outcome of endothelioma, twelve in number. From their nature, growth, and mode of development, blood cysts are most serious conditions, constantly causing great pain and distress, and ever there is an increasing danger of their rupturing into the peritoneal cavity, possibly with fatal results.

In every case of blood cyst that I have had, I have carefully examined with the microscope all other portions of the ovary, and in every instance have found all profoundly diseased, no normal tissue in

No.	Name	Age	State	Number of Cases	Date of Operation	Place	Pathological Conditions	Operation.	Who Present	Adhesions	Result: Recovery or Death	Remarks	Where Reported
1	Miss V. Coming				Oct. 10, 1884	Her home	Pyo-interstitial salpingitis. Uterus in extreme retroversion; ovaries enlarged six or eight times their normal size, dislocated downward, and exceedingly tender, intense oophoritis, in many places commencing suppuration; ova diseased and ruined	Removal of uterine appendages	Drs. W. G. Wylie, J. H. H. Burge, C. N. D. Jones, J. Merrit;	Yes	R.	The patient said she had been sick for seven years; once did not leave her bed for eighteen months. Suffered with extreme pain. It would have been better for the patient if these diseased organs had been removed years before	N. Y. Med. Rec., April 16, 1892; N. Y. Med. Jour., May 14, 1892; Buff. Med. and Surg. Jour., Nov., 1892
2	Mrs. O.		M.		May 25, 1885	My private hospital	Bleeding myoma. Intramural and two subperitoneal fibroids, salpingitis; ovaries more than three times their normal size, and projecting from each one a cyst the size of a hen's egg; acute and subacute oophoritis; few ova and these diseased.	do.	Drs. C. C. Lee, C. N. D. Jones, S. King, F. J. C. Minnard.	Yes	R.	The patient made a rapid recovery; sixth day, pulse and temperature normal; twenty fifth day she left the hospital. When last heard from she was in excellent health.	N. Y. Med. Rec., Aug. 20, 1888
3	Mrs. S. McN.		S.		June 1, 1885	Private hospital	Endothelioma, or alveolar sarcoma of the ovary. Tubes dilated and closed at their unbalanced extremity. For fifteen years the patient had suffered with lacinating pains in the pelvis.	do.	Drs. W. G. Wylie, C. N. D. Jones, S. King	Slight	R.	Many thought the patient would not survive the operation, but after it was performed she gained rapidly in health, strength, and vigor.	N. Y. Med. Rec., Aug. 20, 1885; Buff. Med. and Surg. Jour., Nov., 1892; N. Y. Med. Jour., Sept. 25, 1886.
4	Mrs. H.		M.		Oct. 1, 1885		Pyo-interstitial salpingitis. The transparent attenuated walls of the pus tubes seemed ready to burst; they were bound by firm adhesions to the enlarged and diseased ovaries.	do.	Drs. W. G. Wylie, C. N. D. Jones.	Yes	R.	The patient had constant pain and soreness in the pelvis; for seven years she had suffered; she made an excellent recovery. The husband wrote that "he could not have imagined she would ever be so well."	N. Y. Med. Rec., Aug. 20, 1886
5	Mrs. McK.		M.		Dec. 10, 1885	Ib.	Pyo-interstitial salpingitis. Ovaries small, hard, and nodular, almost the whole normal structure was replaced by cicatrical tissue; endothelioma of the ovary, abscess near the peritoneum.	do.	Drs. C. N. D. Jones, Carey, F. J. C. Minnard.	Yes	R.	Epileptic attacks at every monthly period, patient made an excellent recovery, was up and around at the end of the second week and when last heard from had had no return of the spasms.	do.
6	Mrs. D.		M.		Jan. 1886	do.	Pyo-interstitial salpingitis. In the left ovary an abscess occupying nearly the whole structure, right ovary in a state of intense oophoritis.	do.	Drs. W. G. Wylie, Jones, Ingalls.	Yes	R.	Patient wrote March 2, 1886: "I am feeling perfectly well, never felt better."	do.
7	Mrs.		M.				Pyo-interstitial salpingitis. Each tube was folded and had two distinct sets of fimbriæ, ovaries atrophied and in a state of acute and subacute oophoritis.	do.	Drs. C. N. D. Jones and Ingalls.	Yes	R.	For patient had suffered five years great pain, and disease; not able to attend to her household duties, she made an excellent recovery from the operation, third day, pulse and temperature normal, and since she has had excellent health.	do.
8	Miss L. S.		S.		March 1, 1886		Uterus anteflexed and bound down by adhesions, tubes in a state of salpingitis; ovaries in acute inflammation, the right one contained a hæmatoma.	do.	Drs. Jones and Ingalls	Yes	R.	The patient had been suffering for five years; the operation was attended with great difficulty on account of firm and dense adhesions.	do.
9	Miss E.		S.		April 1, 1886	Ib.	Pyosalpingitis. Abscess in right ovary; oophoritis, waxy degeneration of the arteries.	do.	do.	Yes	R.	For five years patient had suffered with almost constant pain in the pelvis; by operation she was relieved of her suffering and restored to health.	do.
10	Mrs. C.		M.		June 29, 1886	Woman's Hospital of Brooklyn	Pyo-interstitial salpingitis. Ovaries enlarged to three and one-half inches in diameter, each one containing a blood cyst, the rest of the tissue in intense inflammation; in many sections no ova, and the few found were in intense inflammation or waxy degeneration.	do.	Drs. C. N. D. Jones and Caroline Pease			There were adhesions, and tubes were bound down by dense firm adhesions; the patient made an excellent recovery.	N. Y. Med. Rec., Aug. 28, 1886, p. 252.
11	Miss G.		S.		July, 1886	do.	Chronic interstitial salpingitis. Peritonitis; suppurative oophoritis; destruction of the ova.	do.	Drs. C. N. D. Jones and Samuel King	Yes	R.	The patient suffered great pain, was unable to work; after the operation she had excellent health.	
12	Mrs. S.		M.		July, 1886	do.	The patient was brought to the Woman's Hospital with septic peritonitis; the tubes contained pus, and the ovaries were in suppuration.	do.		Yes.	D.	There was apparently no hope when she was brought to the hospital; her whole system was septic.	
13	Miss S.		S.		Jan. 1887	do.	The right ovary containing an abscess was enlarged to three inches in diameter and dislocated low down in Douglas cul-de-sac; ectasia of the lymph vessels; much of the stroma was transformed into a fine globular hyaline mass; ova were destroyed.	do.		Yes	R.	Before the operation the patient suffered constant and intense pain in the pelvis and was not able to perform her daily duties; after the operation she was well and vigorous; third day, pulse and temperature normal.	N. Y. Path. Soc., March, 1887; Am. Jour. Obst., Feb., 1888.
14	Miss Kattie S.		S.		Jan. 26, 1887	do.	Salpingitis. Oophorectic cysts; intense oophoritis, in the dense walls of the cystomatous cysts were found imprisoned delicate nerve fibres; all ova were diseased, some in waxy degeneration.	do.		Yes	R.	The patient had been sick for years; after the operation her health was excellent.	do.
15	Mrs. L.		M.		Jan. 28, 1887	do.	Interstitial and catarrhal salpingitis. Ovaries enlarged, exceedingly sensitive, and low down in Douglas cul-de-sac; endotheliomatous growths extending to the periphery of the ovary; intense oophoritis, no ova; blood-vessels waxy.	do.		Yes.	R.	The patient recovered from the operation without a bad symptom; at the end of the third week was able to assume the burdens of her household duties. March 14, 1887, she was the picture of health, suffering no distress, strong, and able to work; in July, 1886, she had so improved that her physicians did not recognize her.	N. Y. Med. Jour., May 14 and 21, 1892, case 7; Am. Jour. Obst., Feb., 1888.
16	Mrs. M.		M.		March 9, 1887	do.	Bleeding myoma of the uterus. Hemorrhage for the last five months without a day's intermission, appendages diseased; inflammation of the ova and salpingitis.	do.		Yes.	R.	The patient made an excellent recovery; said "she had not been so well for twenty years."	Am. Jour. Obst., Feb. 1888.

Number of Case	Name	Age	Single or Married	Number of Children	Date of Operation	Place	Pathological Conditions	Operation	Who Present	Adhesions	Result: Recovery or Death	Remarks	Where Reported
12	Mrs. N.	..	M	3	March 14, 1887	Woman's Hospital of Brooklyn.	Suppurative parenchymatous salpingitis. Ovaries in intense inflammation; in some places commencing suppuration; large gyromatous cysts; endothelomatous growths; ova diseased and ruined.	Removal of uterine appendages.	.....	Yes.	R.	The uterus retroverted; the appendages enlarged, sensitive; and low down in Douglas' cul-de-sac; the patient made an excellent recovery; the temperature the second day after the operation was three-fourths degree better than the day before, and the third day it was normal, which it had not previously been for months.	Am. Jour. Obst., Feb., 1888.
13	Mrs. S.	..	M	1	April 6, 1887.	do.	Chronic interstitial salpingitis. Peritonitis; acute and subacute oophoritis.	do.	....	Yes.	R.	Her whole system was becoming septic; she made an excellent recovery.	do.
14	Mrs. C.	..	S	0	April 11, 1887.	do.	Each ovary enlarged into a blood cyst. Endothelioma changing to angioma and hematoma, remaining tissue of the ovary was in intense inflammation; only two ova were found, and they were in waxy degeneration.	do.	....	Yes.	R.	The patient suffered for years with intense pain in the pelvis; after the operation she gained in strength, health, and flesh, and wrote, June 4, 1889. "I am in perfect health, after fifteen years of suffering."	N. Y. Med. Jour., Sept. 6, 1890; Buff. Med. Jour., Nov., 1892.
15	Mrs. L.	..	M	2	April, 1887	...	Pyo-interstitial salpingitis. Suppurative oophoritis; tubes were enlarged and contained pus; small abscess in the walls of the tubes; tubes and ovaries bound down by dense adhesions.	do.	.. ..	Dense and thick	D.	The patient had been sick twenty years; had had repeated attacks of peritonitis, and specific constitutional disease rendered her whole system septic.	
16	Mrs. L.	..	M	..	April 12, 1887	do.	Blood cyst in the ovary. Endothelioma; intense oophoritis; waxy degeneration of the ova; mental disturbance.	do.	Dr. C. N. D. Jones.	Adhesions	R.	The patient had suffered for some years, was unable to attend to her household duties; after the operation she regained her health and improved in mental condition.	
17	Mrs. L.	..	M	..	April 13, 1887	do.	Pyo-interstitial salpingitis. Pelvic peritonitis; right ovary and tube were high up and adherent; left ovary and tube also fixed by firm adhesions, and in some places bound to the colon and to the appendix vermiformis. In the ovary, endothelomatous growths, gyromatous cysts; intense oophoritis; ova in waxy degeneration	do.	do.	Dense	R.	For five years the patient had suffered intense pain in the pelvis; she was emaciated, feeble, and not able to go around; after the operation she gained rapidly in strength and vigor, and was able to attend to her daily vocations.	N. Y. Path. Soc.
18	Mrs. L. Webster	..	M	3	May 13, 1887	do.	Both ovaries were enlarged, prolapsed and painful to the slightest touch. Each contained a forming blood cyst; endothelioma changing to hæmatoma; portions of both ovaries were in a state of myxomatous degeneration, some portions showing intense oophoritis; ova were all diseased and ruined, not a normal one in either ovary; salpingitis of the tubes.	do.	do.	Slight	R.	The patient came with her mother to consult me, March 30, 1887; she was pale, emaciated, cachectic, and had apparently tuberculous consumption; she said she had constant pain on each side of the pelvis, severe, sharp, and lacinating, and that she had suffered for years.	N. Y. Path. Soc., May, 1887; Dec. 12, 1888. N. Y. Med. Jour., Sept. 28, 1889; Buff. Med. and Surg. Jour., Nov., 1892.
19	Mrs. M. Carol Gerthes	..	M	8	May 14, 1887	do.	Left ovary enlarged into a blood cyst. Right ovary, cavernous angioma; small lakes of blood, or endothelioma changed to hæmatoma. Other portions of the ovary were intensely inflamed.	do.	do.	Adhesions	R.	The patient was emaciated, cachectic, and had all the appearance of phthisis; after the operation she was relieved of pain, gained flesh and strength, and was able to do the household work and washing for a family of eight persons; hernia was developed.	N. Y. Path. Soc., Sept., 1887; Dec. 12, 1888. N. Y. Med. Jour., Sept. 28, 1889; N.Y. Med. Rec., Sept. 6, 1890; Buff. Med. Jour., Nov., 1892.
20	Mrs. L.	..	M	..	May 16, 1887	do.	Both ovaries enlarged, prolapsed, and extremely sensitive; the right, pear shaped, measured two inches in diameter, and both were filled with an endothelioma tous growth in a far-advanced stage; lakes of blood corpuscles; the ova in both ovaries were ruined.	do.	do.	do.	R.	Before the operation the patient complained of distress and cramps, and extreme pain in the pelvis; not able to be around; she made an excellent recovery, and wrote: "I am able to work and am entirely well."	N. Y. Med. Jour., Sept. 28, 1889; N. Y. Path. Soc.
21	Mrs. ..	..	M	..	June .., 1887	do.	The uterine appendages were bound down in dense adhesions from repeated attacks of peritonitis. Pyo-salpingitis and oophoritis.	do.	do.	Dense	R.	The patient had been sick twenty years; after the operation her condition greatly improved.	
22	Mrs. V.	..	M	..	June .., 1887	do.	Suppurative oophoritis and gyroma. The rest of the ovarian structure was in intense inflammation.	do.	do.	Adhesions.	R.	The patient was weak and feeble, and suffered with constant pain in the pelvis; after the operation she gave every indication of good health, both of body and mind.	
23	Mrs. L.	..	M	..	June 17, 1887.	do.	Ovarian cystoma.	do.	do.	do.	R.	The patient made a good recovery.	
24	Mrs. H.	..	..	..	June 20, 1887	do.	Pyo-interstitial salpingitis. Tubes full of pus; adhesions so large and firm that many had to be ligated and cut. In the walls of the tubes and in the peritoneum were many miliary abscesses, ovaries in intense inflammation; large gyromatous cysts; walls waxy; no ova.	do.	Dr. A. M. Jacobus.	Very dense.	R.	The patient complained of constant pain in the pelvis, sometimes agonizing; unable to perform any kind of labor; fourth day after the operation, pulse and temperature normal.	N. Y. Path. Soc., Sept. 28, 1888.
25	Mrs. L.	..	M	..	July, 1887.	do.	Pyo-interstitial salpingitis. Ovaries enlarged, extremely sensitive, and with the adherent tubes dislocated low down behind a retroverted uterus; intense acute and subacute oöphoritis; gyromatous formations; diseased ova.	do.	do.	Dense	R.	The patient complained of constant pain and distress in the pelvis; was not able to be out of bed; pulse, 120; temperature, 101° F.; weighed seventy pounds; had indications of insanity, talked of self-destruction; after the operation her mental and nervous conditions improved.	N. Y. Med. Jour., May 10 and 17, 1890, case 11; Buff. Med. and Surg. Jour., Nov., 1892.
26	Mrs. Kate Helm	..	M	0	July 18, 1887.	do.	Pyo-interstitial salpingitis. The uterine appendages wrapped in a dense mass of adhesions, and adherent to the alimentary canal and to the appendix; tubes contained pus, and the pseudomembranous adhesions were in intense inflammation; in many places abscess formations; each ovary contained a blood cyst, fibroma, and waxy ova; diseased blood-vessels.	do.	Dr. Brush.	Very dense.	D.	The patient said she had suffered for nine years, and so much that she had often rolled on the floor in agony; the pus formations with the specific constitutional disease produced a septic condition of the system.	N. Y. Med. Jour., May 6, 1890, case 6.

37	Mrs. R.	34	M.	9	August 13, 1887.	Woman's Hospital.	The uterine appendages were wrapped in a dense mass of adhesions, and in the adhesions were many points of suppuration; tubes contained pus, closed at the fimbriated extremity, scarce a trace of the fimbria left; ovaries were in a state of acute inflammation and contained gyromatous formations, some of them waxy, some breaking down into endothelioma; there were no ova.	Removal of uterine appendages.	Dr. C.	N. D. Jones.	Very dense	R.	Constant distress, not able to attend to her daily duties; after the operation she was free from pain and able to work.	N. Y. Path. Soc.
38	Mrs. D.	..	M.	9	Sept. 6, 1887.	do.	Pyo-interstitial salpingitis. The tubes closed and contained pus; muscle fibres of the wall reduced to inflammatory corpuscles, in many places approaching suppuration; miliary abscesses, especially near the periphery; ovaries enlarged, one the size of a goose egg, and each one contained a blood cyst. One formed part of the wall of an abscess cavity. Some of the bands of adhesions were ¾ inch wide; ova in colloid degeneration.	do.		do.	do.	R.	Suffered constant pain and distress in the pelvis; not able to attend to her household duties; after the operation she was free from pain, and able to work; her health excellent.	N. Y. Path. Soc., Sept. 4 and 28, 1887; N. Y. Med. Jour., Sept. 28, 1889, case 7.
39	Hultm..	..	M.	9	August 10, 1887.	do.	Dermoid cyst in the right ovary. Ovary tightly wedged deep into the pelvis, and bound on all sides by firm adhesions; the right tube size of a lemon, full of pus, all traces of fimbria gone, and adherent on all sides, especially by old dense adhesions to the posterior part of the uterus; a large blood cyst in left ovary; also bound to the uterus and to the pelvic wall by firm adhesions. The left tube enlarged as the right and filled with pus, and the tube firmly bound to the uterus and to the walls of the pelvis.	Removal of dermoid cyst.		do.	do.	R.	The patient said she had been sick for fifteen years; after the operation she regained her strength and was able to work; said she scrubbed and washed and so produced hernia.	N. Y. Path. Soc., Sept. 28, 1887.
40	Mrs. H.	..	M.	9	Sept. 8, 1887.	do.	Pyo-interstitial salpingitis. Intense oophoritis; inflammation of the left ovary approaching an abscess; in the right ovary, hæmatoma and intense inflammation; very few ova and these ruined by disease.	Removal of uterine appendages		do.	Dense.	R.	Patient suffered, not able to do anything; after her operation she was free from pain, strong, and well.	
41	Mrs. I.	..	M.	9	Oct. .., 1887.	do.	The uterus in extreme retroversion, dragged down by enlarged ovaries so sensitive that the slightest touch gave distress, and increased pressure caused fainting and convulsions; intense oophoritis, gyroma, waxy degeneration of the ova.	do.		do.	Slight.	R.	Patient made an excellent recovery, gained strength, and was able to work.	N. Y. Med. Jour., May 15 and 17, 1897, case ..
42	Mrs. I.	..	M. yrs.	9	Oct. .., 1887.	do.	Chronic salpingitis. The tubes and ovaries wrapped in a mass of dense adhesions. Some were 4 inches in length and 1½ inches wide. Ovaries were atrophied to less than one-third their normal size; destruction of the ova; the menstrual periods ceased at the age of twenty-five.	do.		do.	Thick.	R.	The patient was emaciated and feeble, and complained of constant distress in the pelvis; after the operation she greatly improved in strength and vigor; left the hospital comfortable and in good condition.	N. Y. Path. Soc., Nov. .., 1887.
43	Mrs. Kid dinger.	..	M. yrs.	9	Oct. .., 1887.	do.	Uterus retroflexed and retroverted. Ovaries enlarged, prolapsed, and extremely sensitive; one, size of a small orange, contained a blood cyst; the other contained a large endotheliomatous growth which extended to the periphery; there were few ova, and they were diseased.	do.	Dr.	Willie Douglas.	Adhesions	R.	Patient said she had been sick for six years, had constant pain in the pelvis, the distress increasing; after the operation she spoke of her improved condition, that she was well, able to work, and glad that she had had the operation.	N. Y. Med. Jour., Sept. 28, 1889, case 5.
44	Mrs. I.	..	M.	9	Oct. 24, 1887.	do.	Pyo-interstitial salpingitis. Intense oophoritis; ovaries enlarged, prolapsed below the fundus of the retroverted uterus.	do.		do.	Dense.	R.	The patient suffered with pain, weakness, and constant distress in the pelvis; since the operation she says her health has never been better.	
45	Mrs. B.	..	M.	9	Oct. 24, 1887.	do.	Hæmatoma or blood cyst in each ovary. Intense oophoritis; both ovaries bound in with adhesions; peritonitis; peritoneal salpingitis.	do.		do.	do.	R.	Patient suffered intense pain, was weak and emaciated; by the operation she was relieved of her suffering, and gradually gained health and strength.	
46	Margaret Fisher.	..	M.	9	Oct. 24, 1887.	do.	Both ovaries enlarged, prolapsed, and exceedingly sensitive; tubes swollen to more than an inch in diameter, full of blood, and in a state of interstitial and catarrhal salpingitis; ovaries in intense inflammation, and contained fibromatous formations; ova diseased.	do.	Dr. C.	N. D. Jones.	Adhesions.	R.	The patient said she had pain in the pelvis all the time, so severe that she could not attend to her household duties; after the operation she repeatedly spoke as to "how improved were her conditions," and "how glad she was that she had had the operation."	N. Y. Med. Jour., May 15 and 17, 1897, case 2.
47	Mrs. I.	38	M.	9	Nov. 1, 1887.	do.	Pyo-interstitial salpingitis. Ovaries in intense inflammation; tubes and ovaries in the midst of inflammatory adhesions, in some places forming abscesses; some adhesions ¾ inch wide.	do.		do.	Dense.	R.	The patient complained of intense pain in the pelvis, was sick and not able to work; after the operation she said she was free from pain, able to work, and had excellent health.	N. Y. Path. Soc.
48	Mrs. I.	35 yrs.	M.	2	Nov. 1, 1887.	do.	Bleeding intramural myoma; weight, nine pounds. Chronic salpingitis, atrophy of the tubes; inflammation of the peritoneal membrane, oophoritis; gyromatous formations; blood-vessels diseased; ova in waxy degeneration.	Hysterectomy	.....		do.	R.	Patient had severe pain, was prostrated, weak, and incapable of any kind of labor; after operation she said she was better and more comfortable than she had been for twenty years.	N. Y. Path. Soc., Nov. 28, 1887; N. Y. Med. Jour., Aug. 28, 1888; Am. Jour. Obst., vol. xxviii., No. 4, 1893.
49	Mrs. H.	..	M.	9	Nov. .., 1887.	do.	Peritonitis, salpingitis, and oophoritis.	Removal of uterine appendages	Dr. C.	N. D. Jones.	Adhesions	R.	Complained of pain in the pelvis, and not able to work; after the operation, patient said her health was restored.	
50	Mrs. H.	..	M.	9	Nov. .., 1887.	do.	Uterus misplaced; tubes contained pus, ovaries enlarged, prolapsed, and in acute inflammation.	do.		do.	Dense.	R.	Patient suffered great distress; after the operation she had excellent health.	N. Y. Path. Soc.
51	Mrs. Hoff..	..	M.	9	Jan. 4, 1887.	do.	Spleen considerably larger than the ninth month of pregnancy; abscess of the left kidney perforating into the left colon descendens; pus, granular, and waxy casts in the urine.	Splenectomy.		do.	Adhesions	D.	The patient was extremely weak; the operation was only an effort to save her.	

Number.	Name.	Age.	State.	Number of Children.	Date of Operation.	Place.	Pathological Conditions.	Operation.	Who Present.	Adhesions.	Results. Recovery or Death.	Remarks.	Where Reported.
47	Miss I.				Jan. [illegible] 1888	House.	Salpingitis, oophoritis, endothelioma of left side.	Removal of uterine appendages.	Dr. C. N. D. Jones.	Adhesions.	R.	Her condition was deplorable, more and more her general health	
48	Mrs. V.		M.		Jan. [illegible] 1888	Wareham's Hospital.	Pyosalpinx interstitial salpingitis. Peritonitis; peritoneal abscess; tubes larger than the ovaries, and full of pus; abscess in the cortex of the left ovary; both ovaries in intense inflammation, and in many places approaching an abscess; ova broken up into medullary and colloid corpuscles.	Removal of uterine appendages.	....	Dense.	R.	Patient suffered intense pain, not able to be out of her bed, after operation she was free from pain and health restored.	N. Y. Med. Jour., Sept. 25, 1886, case.
49	Miss L. [illegible] bands.		M.		Jan. [illegible] 1888		The uterus, tubes, and ovaries were found in one solid mass six inches in diameter and fixed in the pelvis by dense adhesions; some portions of this mass gave evidence of fluctuation, which proved to be a large pelvic abscess and near by a number of smaller abscesses. The left tube measured ten inches in length, and some portions four inches in diameter, was bound by extensive and firm adhesions to the rectum and pelvic wall; ovaries were in intense acute inflammation; large portions of the normal structure destroyed by an endotheliomatous growth.	do.	Dr. C. N. D. Jones.	Very dense.	D.	Her whole system was septic from the large pus formation, and the repeated attacks of suppurative peritonitis.	
50	Mrs. [illegible]		M.		Feb. [illegible] 1888		Pedunculated ovarian cyst.	do.	.....	Small.	R.	Patient relieved of distress, and able to attend to her daily duties.	
51	Mrs. D.		M.		Feb. [illegible] 1888	do.	Pyosalpingitis. Peritoneal abscess, an Iliac abscess in the cortex of the ovary, ovaries enlarged and purulent, uterus cephalic, hematoma, cystoma, and waxy degeneration of the ova.	do.	Dr. C. N. D. Jones.	Dense.	R.	The patient was pale, hectic, frail cachectic, not able to work, suffered so that she sometimes vomited on the floor in agony, after the operation she was able to eat a hearty breakfast.	
52	Mrs. [illegible] Mahlstrom.		M.		Feb. [illegible] 1888	do.	Intramural fibroid tumor, fourteen pounds, with subperitoneal fibroids weighing over seventeen pounds; right tube in loops, 3½ inches in circumference, and filled with bloody serum, left tubes inches long, and filled with pus, both ovaries in acute and subacute inflammation; ova ruined.	Panhysterectomy.	do.	Very dense.	D.	Patient was by her self-sacrificial treatment that she had, she could be brought, after operation, she was relieved of distress and was able to be up on the twelfth day.	N. Y. Path. Soc., N. Y. Med. Jour., Vol. [illegible] Sept. [illegible]; Am. Jour. of Obst., [illegible] Nov., 1892.
53	Miss M.				March [illegible] 1888	do.	Pyosalpingitis and oophoritis.	Removal of uterine appendages.	do.	Adhesions.	R.	After the operation she was free from pain and able to work.	Pittsburg Medical Review, Oct., 1896, case 1.
54	Mrs. J.		M.		March [illegible] 1888	do.	Salpingitis. Endothelioma of the ovary extending to the periphery; a forming hæmatoma; no ova.	do.	do.	Dense.	R.	Patient suffered intensely; after operation free from pain and regained her health.	
55	Mrs. McPh[illegible]		M.	4	March [illegible] 1888		Cancer in the floor of the pelvis. The uterus and appendages fixed by adhesions on the extreme right; tubes and ovaries chronically diseased, and now infiltrated with cancer.	Removal of cancer and uterine appendages.	do.	do.	R.	The patient made an excellent recovery from the operation, but at the end of thirteen months there was a return of the malignant disease.	Pitt. Med. Rev., Oct., 1896; N. Y. Med. Rec., March 21, 1896, case 2.
56	Miss E.			0	March [illegible] 1888		Salpingitis and oophoritis, with myxomatous degeneration of the ovary; necrova.	Removal of uterine appendages.	do.	Adhesions.	R.	The patient suffered viciously, not able to attend to daily duties; after operation she regained her health.	
57	Mrs. Hende[illegible]		M.		March [illegible] 1888	do.	The left tube was enlarged to a blood cyst, size of an orange, adherent to the retroverted and retroflexed uterus, and to the accompanying ovary, and to the walls of the pelvis.	Removal of blood cyst.	do.	Dense.	R.	The patient was weak, prostrated and in great distress, the pain in the back and pelvis were increasing and unbearable, she was able to leave the hospital in three weeks, relieved of distress, and since has been perfectly well.	
58	Mrs. [illegible] Mc[illegible]				April [illegible] 1888		Uterus in extreme retroversion, in front of it, and adherent to the pelvis, was a large sensitive mass three inches in diameter, which proved to be a growing ovarian cyst, it was the right ovary. The left ovary was low down in Douglas' cul-de-sac, in a state of acute and subacute inflammation; the ova of both ovaries were diseased and ruined; suppurative salpingitis of the mucosa and interstitial salpingitis of the tube wall.	Removal of uterine appendages.	do.	Adhesions.	R.	Before the operation the patient wrote: "I have years I have not had a well day, and the pain increases me so I cannot work. After the operation she was able to work, and wrote: "I am glad the diseased ovaries are removed."	N. Y. Path. Soc., April [illegible], 1895; Pitt. Med. Rev., Oct., 1896, case 3; N. Y. Med. Jour., May 1, and 15, 1897, cases.
59	Mrs. L.		M.		May [illegible] 1888	do.	Pyosalpingitis. Peritonitis; oophoritis.	do.	do.	do.	R.	The patient was an invalid for many years from diseased uterine appendages; after their removal she had excellent health and was able to attend to her household duties.	
60	Mrs. Offelb[illegible]		M.		May [illegible] 1888	do.	The uterus was retroflexed and retroverted, and bound down by firm adhesions and by adherent uterine appendages. The right ovary, in intense inflammation, it with the tube formed part of the wall of an abscess which extended into the adjoining pelvis aponeurosis; salpingitis; repeated attacks of peritonitis; the ova were ruined.	do.	do.	do.	R.	The patient said she had constant distress, that her sufferings were so great she could not stand it; after the operation she was relieved from pain and gradually regained her strength and vigor.	Pitt. Med. Rev., Oct., 1896, case.

69	Miss A Memmen		S.	o	June, 1888	Woman's Hospital	Interstitial salpingitis. Abscess in the wall of the tube; ovaries in uterine inflammation, and contained an endotheliomatous growth; in many sections of the right ovary no ova were found; in the left ovary, the ova were waxy and contained medullary corpuscles.	Removal of uterine appendages	Dr. C	N. D. Jones.	Adhesions.	R.	Before the operation she said her life was a misery; after the operation she seemed to be in excellent health, and wrote, July 1, 1898: "I am very thankful that the diseased organs are removed."		
70	Mrs. Schultz		M	o	June 4, 1888	do	Intraligamentous cyst, 9 to 12 inches in diameter, occupying the centre of the abdomen; uterus pushed far to the right, and to it attached thinnest by firm fibrous adhesions; chronic peritonitis; tubes and ovaries gave evidence of long existing disease and repeated attacks of inflammation.	Removal of intraligamentous cyst	do.	do.		R	The patient said she had been sick for many years, the last five incapable of any kind of employment, said the tumor was increasing in size, and her health failing more and more; fifth day after the operation, pulse and temperature normal, patient up the tenth day.		
71	Mrs. Sarah [illegible] Bates	M	[illegible] yrs.		June [illegible], 1888.	do	Pyo-interstitial salpingitis. Uterus retroverted and fixed by a dense mass of inflammatory adhesions. From long existing disease, and repeated attacks of peritonitis, the ovaries and tubes were buried in firm, thick, well-organized adhesions. The left uterine appendages were especially enlarged and formed a tumor-sized of an orange; right so completely covered that they could not be removed.	Removal of uterine appendages on one side	do.	do.	Disease.	D	Patient said she had been married twenty-six years, had been an invalid for more than twenty years, constant and severe pain in the pelvis rendered life a misery; she said she was unable to work, and that the marital relations were most distressing.		
72	Miss M [illegible]		S.	o	June [illegible], 1888	do	Intense pyo-interstitial salpingitis, terminating in atrophy of the tube wall; uterus acutely anteflexed and retroverted; both ovaries and tubes were found bound down by dense adhesions, and forming with the pelvic wall on the left side an abscess. The opening into the wall of the left ovary by an abscess was one inches in diameter, the ova were scanty, and those found were broken up in medullary corpuscles.	Removal of uterine appendages.	do.	do.		R	The patient said she had suffered for years with intense soreness and burning in the pelvis, that rendered her unfit for the active duties of life; she made a rapid recovery from the operation, and subsequently was in the enjoyment of excellent health.	Pitt. Med. Rev., Oct., 1898, case 1.	
73	Mrs. [illegible]		M	[illegible]	June [illegible], 1888	do	Interstitial salpingitis. Ovaries enlarged, prolapsed, and exceedingly tender; both ovaries and tubes wrapped in dense adhesions; the ovarian fibroma degraded by cystic endotheliomatous growths, hæmatoma, gyromatous cysts, the ova in waxy degeneration.	do	do.	Adhesions.	R	The patient said she suffered with such pain in the pelvis that she could not attend to her household duties; she made an excellent recovery and regained only expected her thanks that she was relieved of suffering and the use.		
74	Mrs. [illegible]		M	[illegible]	[illegible]	do	Uterus in extreme retroversion held down by large dilated and adherent tubes; the cavities of both enlarged cystoid cavities, almost entirely filled with tense inflammation, in the cystoid tissue gyromatous cysts and waxy ova, suppurative.	do	do.	[illegible]	R	Patient said she was unable to walk or be out of bed. Her husband wrote, May [illegible], "I believe the operation and treatment has saved my wife's life. Her recovery is perfect in both health and strength."	Pitt. Med. Rev., Oct., 1898, case 9. N. Y. Med. Jour., May [illegible], 1898, case 4.	
75	Mrs. H [illegible]		[illegible]	do	[illegible]	do	Vessel the ovarian cyst-wall was converted into and bordered on an abscess cavity, the walls of which cavity were completed by the floor of the pelvis, right ovary in myxomatous degeneration; both ovaries and tubes bound in with adhesions; salpingitis; ova in waxy and fatty degeneration.	do	do.	do.	R	Patient said she had constant pain, burning heat, and bearing down in the pelvis; that at times she was not able to walk, and could not even draw a long breath without causing her pain and distress; she made an excellent recovery, and was entirely relieved of the old pain and suffering.	Pitt. Med. Rev., Oct., 1898, case 6.	
76	Mrs. Eng [illegible] [illegible]		M [illegible]	[illegible] yrs.	[illegible]	do	Intramural myoma, subperitoneal fibroids. The patient was apparently done well, and everything seemed satisfactory, when some hours afterward the heart's action became irregular, the patient had for eight years suffered with heart disease; her husband said, "sometimes she could hardly breathe."	Hysterectomy	do.	Disease.	D	An acute attack of peritonitis. The patient had had uterine tumors for years, but suffered only the last few months, after she had had electrical treatment.	N. Y. Path. Soc.	
77	Mrs. [illegible]		M	[illegible]	Sept. [illegible], 1888	do	Pyosalpingitis. The anteflexed uterus fixed on the right by dense adhesions, which adhesions covered in the right tube and ovary, and enclosed a large abscess cavity filled with pus; destruction of the ova.	Removal of uterine appendages.	do.	do.		R	The patient said she had constant pain and distress in the pelvis, so severe that she had to go home over and not able to attend to her house-hold duties, after the operation she was relieved of pain and was strong and vigorous.	Pitt. Med. Rev., Oct., 1898, case 2.	
78	Mrs. W [illegible]		M	[illegible]	Sept. [illegible], 1888	do	Uterus fixed on the right by repeated attacks of peritonitis; right ovary enlarged by fibroid growths; left ovary, acute and subacute oophoritis, chronic salpingitis.	do	do.	do.		P	The patient had been sick nine years, was pale, feeble, and emaciated, she had constant distress in the pelvis; after the operation she was relieved of pain and resumed her health and vigor.	N. Y. Path. Soc., Sept. 23, 1897, Dec. 17, 1898; N. Y. Med. Jour., Sept. 17, 1898, case 5; Buff. Med. and Surg. Jour., Nov., 1897; N. Y. Med. Jour., March 12, 1898.	
79	Mrs. S [illegible]		M.	[illegible]	Nov. [illegible], 1888	do	Pyo-interstitial salpingitis. Oophoritis; much of the ovarian tissue destroyed by endotheloma and cystoma.	do	do.	Adhesions.	P	Patient said she suffered most distressing pain, so acute and constant that she could not attend to her daily duties.		
80	Mrs. A [illegible]		M	[illegible]	Nov. [illegible], 1888	do	Pyosalpingitis. Uterus anteflexed and retroverted, ovaries enlarged and prolapsed; in each were endothelomatous growths and gyromatous cysts, ova in waxy and colloid degeneration.	do	do.	do.	R	Patient made an excellent recovery, was free from pain, and able to work.		
81	Miss W [illegible]		[illegible]	[illegible]	Nov. [illegible], 1888	do	Both ovaries enlarged to blood cyst from endothelomatous growths.	do	do.	do.	P	The patient was feeble, emaciated, and cachectic, said she had been sick for more than a dozen years and continued to grow worse; she made an excellent recovery, and subsequently wrote that she was regaining her health, strength, and flesh.		
82	Mrs. [illegible]		[illegible]	[illegible]	Nov. [illegible], 1888	do	Bleeding intramural myoma, as large as a fetus at the fourth month, of several small subperitoneal fibroids. Ovaries and tubes in chronic inflammation.	do	do.	do.	L	The patient said she had been an invalid for many years, and was exhausted by repeated uterine hemorrhages; she made an excellent recovery, and has since written that she "is in excellent health."		

Number.	Name.	Age.	State.	Number of Children.	Date of Operation	Place	Pathological Conditions	Operation	Who Present.	Adhesions	Result, Recovery or Death.	Remarks	Where Reported.
1	Mary Gar...	23	S.	0	Dec. ..., 1888	Woman's Hospital	Pyo-interstitial salpingitis. Peritonitis; one ovary enlarged into a blood cyst the size of an orange, and covered with inflammatory adhesions, the ovary on the opposite side not so large, but gave equal indication of disease, and with its corresponding tubes found in dense adhesions; in many sections there were no ova, and those found were diseased.	Removal of uterine appendages	Dr. C. N. D. Jones.	Adhesions.	R.	Complained of constant and distressing pain in the pelvis; after operation she was relieved of pain, able to work, and the epileptic attacks were less frequent	Med. and Surg. Rep. Phila., May 22, 1897.
2	Mrs. ... (Colored)	...	M.	...	Jan. ..., 1897.	do.	Salpingitis and commencing cystoma	do.	do.	do.	R.	By the operation the patient was restored to health.	
3	Miss M.	...	S.	...	Jan. ..., 1897.	do.	Interstitial salpingitis. Intense oophoritis; abscess; in many sections no ova, those found were ruined	do.	do.	do.	R.	The patient suffered so much that she could not attend to her duties; she was anxious to have the operation, and was relieved by it.	
4	Miss H.	...	S.	1	Jan. ..., 1897.	do.	Salpingitis. Hæmatoma; oophoritis; diseased ova	do.	do.	...	R.	Constant pain in the pelvis so she could not attend to her duties; after the operation, free from pain and able to work.	
5	Mrs. H.	...	M.	1	Jan. ..., 1897.	do.	Misplaced and diseased ovaries.	do.	do.	do.	R.	The patient made an excellent recovery and regained her health and strength.	
6	Miss W.	...	S.	...	Jan. ..., 1897.	do.	Interstitial salpingitis. Oophoritis; cystoma; waxy blood-vessels; no ova; colloid corpuscles in the cortex.	do.	do.	do.	R.	Patient suffered constant pain and distress, not able to attend to her duties; after operation, relieved of pain, and when last heard from was still improving.	
7	Mrs. S.	...	M.	1	Jan. ..., 1897.	do.	Chronic pyosalpingitis. Peritonitis; both ovaries enlarged and prolapsed, one giving evident fluctuation and containing an abscess.	do.	do.	do.	R.	The patient complained of great distress and suffering, of which she was relieved by the operation.	
8	Mrs. S...	...	M.	1	Jan. ..., 1897.	.....	Abscess in one ovary. In both fibromatous formations and oophoritis; no ova found; chronic salpingitis	do.	do.	Dense.	R.	The patient said for years she had pain in the region of the ovaries, and constantly such distress that she did not feel able to walk or perform her household duties.	N. Y. Med. Jour., May 1, 1897.
9	... H.	...	S.	...	Feb. ..., 1897.	Woman's Hospital	Pyo-interstitial salpingitis. Uterus anteflexed and retroverted; ovaries enlarged and prolapsed and in a state of intense inflammation.	do.	do.	Adhesions.	R.	The patient said she had constantly cutting pains in the pelvis, sometimes would fall down in agony; after the operation she was relieved of pain and expressed herself frequently as to her improved condition.	
10	Mrs. A. H.	...	M.	1	Feb. ..., 1889.	do.	Pyo-interstitial salpingitis; oophoritis.	do.	do.	do.	R.	Complained of constant and severe pain in the pelvis; said by the operation she was relieved.	
11	Mrs. E.	...	M.	...	Feb., 1897.	do.	Interstitial salpingitis. Acute and subacute oophoritis; ova in waxy degeneration.	do.	do.	do.	R.	By the operation she was relieved of distress and pain.	
12	Mrs. Ida L. Hoag.	...	M.	1	Feb. ..., 1897.	do.	On the left the ovary enlarged to a blood cyst the size of a small cocoanut and exceedingly tender; the tubes in a state of chronic salpingitis, and each one adherent to its corresponding ovary.	Removal of blood cyst.	do.	do.	D.	The patient said: "I suffered terribly, and got worse all the time; I have constant distress and severe soreness in the pelvis."	
13	Mrs. H.	...	M.	...	March ..., 1897.	do.	Salpingitis. Intense oophoritis; in each ovary endothelioma tous growths and fibroma; ovarian waxy and colloid degeneration.	Removal of uterine appendages.	do.	do.	R.	Patient said she had been sick for five years; after operation she was well and entirely relieved of pain.	
14	Mrs. S.	...	S.	0	March ..., 1897.	do.	Much of the ovarian tissue was destroyed by an endothelioma tous growth; the ova were ruined; salpingitis.	do.	do.	do.	R.	Patient said for five or six years she had suffered severe pain, and was not able to work; after operation she was well and able to work.	
15	Mrs. S.	...	M.	...	.....	...	Ovarian cystoma, which contained about sixty pounds of fluid.	Ovariotomy.	do.	Slight.	R.	The patient said: "I have been a great sufferer for six or seven years. I am well now and feel first-rate."	
16	Mrs. S.	42	M.	2	Jan. ..., 1897.	Woman's Hospital.	Bleeding intramural myoma. Suppurative interstitial salpingitis; forming abscesses in the walls of the tubes; intense oophoritis, approaching an abscess; peritonitis; in many sections, no ova; the few found were diseased and ruined.	Removal of uterine appendages.	do.	Dense.	R.	Patient was weak and prostrated from continuous hemorrhages; said that for eight years she had suffered intense pain; said October 17, 1896, that she had never felt so well as she had since the operation.	
17	Emma ...	...	M.	...	.....	do.	Pyosalpingitis. Oophoritis; much of the ovarian structure destroyed by endothelioma tous and fibromatous formations	do.	do.	Adhesions.	R.	The patient said: "Before I went to the hospital I had great pain, could not walk, nor was I able to work; now I have no pain, can walk, and attend to my daily duties."	
18	Mrs. K.	...	M.	0	July ..., 1896.	do.	Tubes 2 inches in length, 1½ inches in diameter and full of pus; ovaries converted into blood cyst and bound in with adhesions, wedged down deep into the pelvic cavity.	do.	do.	Dense.	R.	The patient suffered from great and constant pain	
19	Mrs. M.	...	M.	0	.....	do.	Intramural myoma. Salpingitis; oophoritis; suppurating endothelioma; large abscesses in the pelvis.	Hysterectomy	Drs. H. C. Coe, C. N. D. Jones, and O. D. Frey.	do.	D.		
20	Mrs. O.	...	M.	2	.....	Her home.	The left ovary size of an orange, containing a blood cyst; the right in intense inflammation, and much of its structure destroyed by an endothelioma, changing to angioma; pyosalpingitis of the tube in some places, miliary abscesses in the walls; no ova were found.	Removal of uterine appendages.	Drs. R. T. Morris, S. E. Currier, C. N. D. Jones.	do.	R.	For years the patient had complained, and had been under long-continued treatment without benefit; after the operation her health greatly improved.	

any part; and invariably I have found destruction of the ova.

Removal of the uterine appendages for internal myoma, four cases. All made a good recovery. Lawson Tait says[1] that the cases in which he has removed the uterine appendages for myoma were twenty-five in number, with four deaths; and one death in an incomplete operation, making in all five deaths.

Hysterectomy for myoma of the uterus, four cases. The first total hysterectomy ever performed in this country for myoma was Case No. 52.[2] The tumor weighed fourteen pounds after its removal. The patient was able to be up on the twelfth or thirteenth day, and she suffered infinitely less than if the pedicle had been treated intraperitoneally or extraperitoneally. Dr. T. A. Emmet says:[3] "To remove the uterus when enormously enlarged by a fibroid tumor is unquestionably one of the most formidable operations a surgeon can be called upon to undertake." Dr. Lawson Tait says:[4] "Hysterectomy for fibroid is the most ghastly, serious, and difficult operation in the whole realm of abdominal surgery." Dr. C. D. Palmer says:[5] "There are no operations within the domain of surgery more grave;" "the dangers to be encountered are the greatest within the range of pelvic surgery."

By entire hysterectomy the operation is relieved of many of its difficulties, and especially is free from the many dangers of the pedicle treated intra or extra peritoneally.

In this list there were adhesions in eighty cases. Dr. Joseph Price says:[6] "Adhesions constitute the surgeon's greatest difficulty." Sir Spencer Wells said, January 4, 1862, that he looked upon pelvic adhesions as one of the most serious indications against ovariotomy. Dr. Peaslee said:[7] "Adhesions compromise the result of ovariotomy." Erichsen said: "They undoubtedly are a serious obstacle to the success of an operation."

In a few of my patients hernia developed subsequently to the operation, but in every instance this was in hard-working women, who after leaving the hospital commenced at once their heavy labors. One, No. 24, did the household work and washing for a family of eight persons, and sometimes took in the washing for a boat's crew. If these women had taken one-tenth of the care and precaution that a certain physician did after undergoing laparotomy for appendicitis they would have been in no danger of hernia.

Dr. Bantock says:[9] "Cases of hernia after ovariotomy are by no means rare." Joseph Price says:[10] "Herniæ cannot always be avoided, and they are not among the avoidable sequelæ."

Many or most of the operations mentioned in this list were so dangerous that I often marvelled that the patients did so well or made so rapid a recovery. At the same time I am infinitely grieved that any patient under my care died subsequently to operation; but in every instance of a fatal termination there were indications that even without the operation there would soon have been the same result. Some of the cases were undertaken as a forlorn hope. Case No. 49 was one of a large pelvic abscess and abscesses all through the peritoneum; the case was fatal before it was touched, as was also the case of the colored woman (No. 12),[1] who was brought to the hospital with septic peritonitis. Equally fatal beforehand was the case of splenectomy (No. 46). Dr. Charles Heitzmann said, before the operation, from his examination of the urine, that "there is an abscess in one kidney, which abscess opens into the descending colon." Besides, the spleen gave evidence of malignancy. It was foully diseased in every part. Even under the most favorable circumstances removing the spleen is a very dangerous operation. In 1886 there had been in Great Britain twelve splenectomies, and they were all fatal; T. Bryant, of Guy's Hospital, had two subjects, both of whom died from the operation; and Billroth, in Vienna, had performed the operation thrice, each time with a fatal result. The first successful case in Great Britain was that of J. Knowsley Thornton.[2] The patient was a girl, nineteen years old; the spleen weighed one pound eleven ounces—so small that Dr. Thornton supposed it was the left kidney. The spleen of my patient weighed nearly eighteen pounds, and enlarged the abdomen to enormous proportions. There was not the least chance for the patient; but she begged to have the operation performed, hoping that in this last resort she might find relief. As Dr. John Homans[3] says: "A surgeon is bound at times to operate in cases in which he can give but little hope of a favorable result."

All three of these cases might be called "exploratory incisions." Now, if I should, as some have done, give only my "completed operations," this would take off Mrs. Bates, Mrs. E——, and Mrs. Bruggeman, and my mortality would thereby be reduced to about 2.5 or 3 per cent. Then, on the same principle I could exclude one or two cases that died in consequence of specific constitutional disease, which is foreign to the operation and is far more formidable than acute sepsis. Acute sepsis may be relieved by full action of the bowels, but the freest evacuations have no effect upon this chronic mysterious poison. I believe this specific constitutional disease, syphilis, has been the hidden enemy that has increased the death rate of many a surgeon.

In Case No. 86 the patient had a blood cyst, but it was not so dangerous or so complicated as were the blood cysts of patients Nos. 10, 90, and 94; nor was this patient in so weak, dangerous, or precarious a condition as were many patients in this list; and in no respect was it half so difficult, half so serious or dangerous an operation as were Nos. 29, 34, 52, and many others, or even Nos. 83, 84, and 85, who happened to be in the hospital the same time. All these patients made a good recovery, and had subsequently excellent health; but No. 86 had the specific constitutional disease, and though everything was done, every care and precaution known to the best surgeons in this country or in Europe were taken, and though her physicians were with her night and day, studying and doing everything for her recovery, yet she succumbed —died on the sixth day of some kind of blood poisoning. I do not believe any proposed preparation or procedure could have saved her. Her death was, I believe, entirely due to this mysterious blood poison, this specific constitutional taint of syphilis.

Though there were losses, yet by the various opera-

[1] This case was very similar to the one presented by Prof. W. T. Lusk before the New York Obstetrical Society, October 21, 1879—general peritonitis, oöphoritis, abscesses. Dr. Lusk did not do an operation, but the patient died just the same. As Dr. Noeggerath wisely said: "The primary disease was a double salpingitis." So the primary disease in my case was a double salpingitis.

tions in this list many valuable lives were saved; many patients were restored to health who would otherwise have been hopelessly lost. Dr. L. S. Pilcher wrote in 1892 a paper on "The Ultimate Results of Operations for Removal of the Uterine Appendages," referring to the possible "persistence of pain," the possible development of "hernia," of "fæcal and urinary fistula," and the possible sequelæ of "mental disturbances."

None of these sequelæ need follow. In cases in which the conditions demand an operation, there is usually an entire relief of the pain; and in no instance have I seen an operation followed by mental disturbances, when similar mental disturbances or abnormal mental conditions did not previously exist, and in a more exaggerated form or degree. So in proper cases I am prepared to assert that "the ultimate results of the removal of the uterine appendages" are: *Many lives are saved and countless numbers are redeemed from helpless invalidism.* Many who do not recover would probably soon die from existing causes. Prof. William T. Lusk said:[1] "The operation of removing the uterine appendages has been the means of liberating many women from persistent suffering, and has perhaps saved many others from death." Dr. Joseph Eastman says:[2] "Some argue that the operation is being done too often. My limited experience induces me to believe that where the uterine appendages have been unnecessarily removed once, ten women have gone down to the grave whose lives could have been saved by timely removal of the uterine appendages."

DIAGNOSIS AND TREATMENT OF AFFECTIONS OF THE FRONTAL SINUSES.[3]

BY F. FEHLEISEN, M.D.,

SAN FRANCISCO, CAL. (LATE OF BERLIN).

THE diseases of the frontal sinuses offer us an interesting and many-sided picture, and only to outline the same and merely to mention the many mistakes in diagnosis made by physicians familiar with the subject would force me far beyond the limits of this paper. Therefore I shall only briefly name the chief kinds of sinus affections, dwelling somewhat more at length on a diagnostic point of considerable importance, and finally discuss the great advances made in the treatment during the last few years.

In the large majority of cases frontal-sinus affections are caused by infection. The inflammation frequently spreads from the nose to the frontal sinus. However, primary inflammations (usually acute) of the frontal sinus may occur with, or more rarely without, simultaneous disease of the nasal cavities. The former is the case with simple coryza, the latter with certain infectious diseases, especially with measles, scarlet fever, diphtheria, typhoid, pneumonia, influenza, etc. Also syphilis of the nasal cavities can extend to the frontal sinus.

One differentiates according to the kind of infection the following forms: sinusitis catarrhalis, blennorrhoica, and pyorrhoica, and an encapsulated empyema of the frontal sinus. No strict line can be drawn between these different forms, as generally a mixture of mucus and pus and often blood also is found. Frequently thickened crumb-like masses occur. The difference in the clinical pictures is chiefly influenced by the more acute or chronic course of the disease. The more acute cases begin with high fever, sometimes even a chill, followed by severe constitutional symptoms. The sensorium is not clear. Soon perforation occurs, as a rule in the anterior and inferior wall, and an eyelid or orbital phlegmon results. Very rarely it opens posteriorly toward the cranial cavity. The mucous membrane of the sinus is in such cases frequently colored black and is gangrenous, and the exudate ichorus or purulent. Between these very acute cases and the chronic ones, some of which have lasted for years and whose actual beginning cannot be determined, there are many intermediate forms. The most frequent are the chronic forms, the purely chronic as well as those whose course is interrupted by subacute attacks. There are suppurative cases which show no other symptoms except a flow of pus on one side of the nose, lasting for years, and sometimes an occlusion of the nose accompanied by frequent headaches with more or less dizziness. In encapsulated empyema, which can also develop slowly, the flow of pus is of course absent, but the headaches are more pronounced. Often such patients first come under observation when in connection with a common coryza an exacerbation has set in, and the process suddenly assumes a more or less acute character. Other common forms have a more acute beginning. In connection with a coryza a mild sinusitis catarrhalis with slight symptoms develops. With the disappearance of the swelling in the nose, the swollen ductus nasofrontalis opens again, the secretions flow off, and the patient feels well. But every new catarrh is followed by another attack of acute or subacute inflammation of the frontal sinus. After a time the inflammation no longer wholly disappears and chronic disease of the sinus results. This terminates in one of two ways. Either the attacks become more severe and the complaints greater, even between two exacerbations, and in time a pyorrhœa or an encapsulated empyema occurs, according to whether the outlet becomes pervious between the attacks or not; or it may happen that when the outlet is permanently closed the attacks become less and less severe and finally cease. In this case the patient believes himself cured, until at some future period a swelling near the root of the nose, toward the orbit of the eye, is noticed, or disturbances of vision send him to the oculist. The sinusitis catarrhalis becomes a mucocele, which, unlike the empyema, gives no discomfort to the patient, until either the increasing bulging of the forehead near the sinuses or disturbances of vision call his attention to the trouble.[1]

The second etiological factor of sinus diseases is traumatism. A number of reliable cases have been observed in which either a mucocele or an empyema has followed trauma. A blow, with or without fracture of the bone, can cause a flow of blood into the sinus, and a clot is formed which inflames the mucous membrane by irritation. Then, either a sinusitis catarrhalis with closure of the ductus nasofrontalis, followed by the formation of a mucocele, occurs, or a sinusitis pyorrhoica or encapsulated empyema results, according to whether the outlet remains open or not. A third group of sinus diseases, caused by tumors, parasites, and foreign bodies, is simply mentioned because of their rarity.

The diagnosis of the acute cases is, as a rule, easy. Chronic cases on the other hand are often mistaken for supra-orbital neuralgia, migraine, etc. Many cases have been published which were misunderstood for years, and which finally astonished patient as well as physician by perforation taking place through the forehead or orbit. This is chiefly true of those remittent cases in which at intervals of weeks or even months short acute or subacute attacks occur, giving us an

[1] New York Academy of Medicine, March 6, 1890. — Ibid.

[2] Read before the Society of German Physicians, San Francisco, Cal., September 2, 1896.

[1] An exhaustive treatise by H. Krehnt, entitled "Die entzündlichen Erkrankungen der Stirnhöhlen und ihre Folgezustände," gives a detailed account of the various and interesting eye complications.

exact picture of neuralgia. Of course the easiest to recognize are those cases in which there is either a continual flow of pus, or in which the acute attacks stop with the emptying of the sinus.

Pus flowing from one side of the nose should arouse suspicion of disease of one of the cavities opening into the nose. If on closer inspection one sees the pus coming from the anterior end of the thickened middle turbinated bone, it points to frontal-sinus disease. The diagnosis can be made sure by putting a sound into the ductus nasofrontalis and allowing the secretion to escape. In cases of encapsulated empyema this symptom is of course absent, and the diagnosis would become very difficult were it not for one symptom which I consider of great importance, namely, the tenderness of the bone on pressure. That the bone in acute cases is painful, both spontaneously and on pressure, is clear, but in chronic cases also pressure with a thick sound or pencil, percussion with a plexim-eter, etc., will cause pain. Many physicians could by these means draw the limits of the sinuses on the forehead and later at the operation assure themselves of their accuracy. Much more important than this well-known tenderness on pressure of the forehead is the same sign elicited at the floor of the sinus, that is, the upper wall of the orbit, and that is a point to which, as far as I know, our attention has only lately been called with sufficient emphasis by Kuhnt. To understand this, one must know how the bones are affected in these diseases, the process being different according to whether a mucocele or an inflammatory condition is present. In the former (*i.e.*, the mucocele or hydrops) a simple pressure atrophy and distention of the bone follow. It becomes thin and blown out like a bubble, especially the anterior and perhaps still more so the inferior wall. The sinus can contain in this way as much as six ounces or more of fluid. The ethmoid and sphenoid may be pressed downward and the whole orbit pushed out of place. Of inflammatory changes there are no signs. So also in the cases of traumatic hydrops generally and those of cystoid hydrops or mucocele, in the great majority there is no pain. At all events the subjective symptoms are much less than in the purulent process.

Often the first symptom of the mucocele is the bulging of the bone which usually occurs in the upper and inner corner of the orbit. Why just there I shall explain later.

In purulent inflammation of the sinus the bone is altogether differently affected. Here we have to deal not with a pressure atrophy of the bone but with an extension of the inflammation from the mucous membrane to the surrounding bones. As elsewhere, in the immediate vicinity of the inflamed point, a rarefying ostitis sets in, the bone becomes soft, and at length, this process continuing, is perforated. Of course I cannot deny that pressure may also develop in the pus sac, but this does not cause a slow bulging of the bone, but rather an acute attack with severe frontal headache, high fever, and a comatose condition as chief symptoms. These do not subside until either the pressure diminishes, or the pus escapes through the ductus nasofrontalis, or perforation of the bone takes place. In chronic purulent processes the perforation occurs slowly and there is no distention of the bone. A small opening is formed, just as in chronic necrosis of a long bone; a so-called cloaca results, due to purulent dissolution of the bone.

I would not give so much space to this had it not repeatedly happened that one of my colleagues wished to question my diagnosis with the remark that no distention was present. Likewise in the literature of the last few years I find in discussions on empyema that absence of elevation is mentioned as a peculiarity. This elevation is one of the symptoms of hydrops, but not of empyema, in which it is generally wholly absent, except when a case of purulent mucocele is in question.

This perforation very rarely occurs inwardly toward the brain, less rarely toward the forehead, and generally downward through the orbital wall, not only because this is thin, but also, as Kuhnt has endeavored to prove, because it is not so well nourished.[1] Now there are two places in the orbital wall where the perforation usually takes place. One is in the inner and upper corner of the orbit, immediately behind and under the fovea trochlearis; the other somewhat behind the incisura supra-orbitalis. At both of these points the bone is pierced by veins which run from the mucous membrane of the sinus to the vena ophthalmica and supra-orbitalis. Along these vessels the inflammation travels and starts the resorption of the bone. Consequently, if in doubtful cases one wishes to make the tenderness of the bone on pressure of diagnostic value, one must not confine the examination to the frontal wall of the sinus, but must introduce the little finger into the upper and inner corner of the orbit; then the patient is told to look downward and an attempt is made to enter behind the incisura supra-orbitalis. Here the bone is sometimes thin and giving, as the cover of a tin box, or there may be an inflammatory thickening of the periosteum, but almost without exception pressure will be found to be painful. If the examination is conducted in this way, the tenderness on pressure will hardly ever fail to aid in the diagnosis of chronic disease of the frontal sinus. Commonly the tenderness is very pronounced, at times intense.

The illumination of the frontal sinus, advocated chiefly by Vohsen, has not fulfilled expectations. The picture of the normal illuminated sinus is too variegated and often different on the two sides, so that small differences in the transparency of the two sides prove nothing. In very pronounced empyema the diseased side appears darker, but in chronic pyorrhœa both sides may seem equally light; therefore the negative result of the examination proves nothing, though the positive is of some value.

Regarding the therapy, the first attempt to get at frontal-sinus disease in a bloodless way through the nose was made by A. Hartmann.[2]

There are patients who with every severe cold they contract become at the same time affected with sinusitis frontalis catarrhalis and closure of the canalis nasofrontalis. This, according to Hartmann, causes conditions of the frontal sinus similar to that found in the middle ear in closure of the Eustachian tube. Having this in mind, Hartmann endeavored to force air through the canalis frontalis, just as by Politzer's method the Eustachian tube is opened. Although this method is said to have been of value in some of these cases, it has not to my knowledge had many followers. However, the attention of the specialist was drawn to this route, and already in the next decade Jurasz was able to pass a sound from the nose through the ductus nasofrontalis. In this way he not only let the secretions escape, but also by means of syringing and washing out could treat the mucous membrane of the sinus. It is true that the passing of a sound is not possible in all cases, but by this method of Jurasz a large number of early cases of sinus catarrh and suppurative processes can be cured. For acute and phlegmonous cases this method is of no use, as more energetic treatment is necessary. Likewise it is not sufficient for obstinate cases of chronic suppuration and empyema, as in these such changes in the mucous membrane have usually occurred that it can no longer return to its normal state. And here I must say that,

[1] The anterior wall is the strongest; about the same or slightly less so is the posterior wall, and the inferior wall is the thinnest.

[2] Deutsche medicinische Wochenschrift, 1877.

generally speaking, the importance of the obstruction of the ductus nasofrontalis in chronic purulent processes of the frontal sinus is to this day greatly overrated. It is difficult to give statistics about this, as many authors impart no or insufficient information on the subject. There are, however, many reliable cases published in which the disease, in spite of free discharge of the pus through the nose, has lasted for years, and has, even in spite of syringing and flushing, grown worse. I remember a case in which an orbital fistula was present, injected fluid running out through the nose. The case was not cured, although many different agents were used. The fistula closed several times but always reopened. Permission to operate was refused. From what has been said it is clear that a radical surgical procedure from the forehead is indicated in a number of cases, as encapsulated empyema, mucoceles, or hydrops, and those chronic suppurations in which the mucous membranes have been greatly altered, as well as the severe acute phlegmonous inflammations. Now trephining of the frontal sinus is an old operation, but in its original form it was not satisfactory. The simple opening allowed an exit for the inflammatory products and placed the patient out of danger. But the wound remained open as a fistula for a long time, and even if it closed one could not be sure that it would not reopen. With a sinusitis it is not a question of a bone abscess, which after being emptied heals, but of a cavity lined with diseased mucous membrane. And the same is true of this mucous membrane, as, for instance, of the diseased uterine membrane, the membrane lining the lacrymal duct, etc. They are all incapable of returning to a normal state by means of medical treatment, if they have undergone certain great changes. It is perhaps curious that the idea not only to chisel open the sinus, but at the same time to take away the diseased mucous membrane, has not occurred sooner. This was done occasionally formerly. Thus Kuhnt mentions a case of Runge's of the last century in which the membrane was destroyed by chemical agents. More recently Spencer Watson has recommended strong solutions of iodine and Richet aqua juglandis spirituosa for the destruction of the secreting membranes. But it was only in 1890 that Nebinger recommended extirpation of the pituitary membrane after opening the frontal sinus with a chisel.

Nebinger opened the sinus widely from the front, while Jansen three years later proceeded from below through the orbit. Jansen did this more especially to secure the best cosmetic effect. Both methods are rational, as they fully remove the seat of disease and surely effect a cure. However, in the Jansen method a considerable cavity is formed in the bone, which takes a long time to heal. Jansen expected that the fatty tissues of the orbit would fill the empty sinus, but we cannot count on that with certainty, and as a matter of fact his cases need half a year and longer for healing. I can see no advantage in Jansen's method as compared with that of Nebinger, as the cavity cannot be inspected as well if opened from below as when opened widely in front. Jansen actually had to make several secondary operations to remove portions of mucous membrane that had been left. I strongly recommend a modification of Nebinger's method as described by Kuhnt. This consists chiefly in that not only is the sinus opened widely, but also the whole front wall and sometimes part of the lower wall are removed. The bony edges are bevelled as much as possible, so that no bony cavity but as shallow a depression as possible results, to which the soft parts can be pressed by a bandage. This cannot always be done perfectly, but the cavity of the wound can always be reduced considerably, especially as compared with Jansen's operation. In this way the time of treating is very greatly reduced and the cosmetic effects are bettered. I followed Kuhnt's advice in two cases, the one of empyema, the other of sinusitis pyorrhoica chronica, in both of which rapid recovery took place. Both patients were dismissed from treatment at the end of the first month, while my former cases of sinus trephining always took several months, and sometimes would be discharged having a fistula.

In regard to one thing only do I disagree with Kuhnt and that is the indications. Kuhnt first opens the sinus; then after inspecting the mucous membrane decides whether to remove it or to drain in the old way. This last is no longer considered by me, after having seen the more rapid and better results of the radical operation. I deem it self-evident that in early cases it will always be tried to open the ductus nasofrontalis by means of a sound. Even if this is not accomplished the first time, the rhinologist can still attain his object by obtaining a reduction of the swelling of the mucous membrane near the opening of the canalis nasofrontalis, either by removing the anterior thickened part of the middle turbinated or by other procedures which alone have caused early cases to heal.

No patient will submit to an operation after the first or second slight attack of sinusitis catarrhalis. When he finally agrees to it the mucous membrane has undergone changes which, if one desires to save it, will lengthen the duration of treatment and delay the closure of the wound. The greatest disadvantage, however, is the danger of return. On the other hand, if we obliterate the sinus by extirpation of the mucous membrane, then the result is not only sure but quicker. Against this it is of no moment, in my opinion, that the operation may last from ten to twenty minutes longer, or that the scar may be slightly larger, for disfigurement is little dependent on the length of the incision. The more radical the operation the sooner the cure and the more linear will be the scar. I wish now briefly to describe the technique of the operation, in the main points of which I agree with Nebinger and Kuhnt.

As regards the point of chiselling, most operators recommend a place corresponding to the inner end of the eyebrow. It is at the intersection of two lines, one of which connects the two incisuræ supra-orbitales, the other being drawn perpendicular to the first from the crista lacrymalis anterior. The point lies at the margo supra-orbitalis perpendicularly over the ligamentum palpebræ. Nebinger advises to begin chiselling at the os nasæ. I must confess that the fear which many have of opening the skull gives me little worry. In general the frontal bone consists of a tabula externa and a tabula interna, with spongy bone between. The anterior sinus wall consists solely of tabula externa; so if one chisels carefully one can hardly enter the cranial cavity, as one will see the spongy bone and be warned. Having chiselled through the sinus wall, the mucous membrane will appear as a dark red or perhaps discolored yellowish or black cyst, provided that it has not been destroyed by gangrene.

Not infrequently the sinus contents pulsate, which in no way points to a defective posterior wall of the sinus, but, as Boeckel showed, is always present when a bony-walled cavity is opened in which there are tissues containing many vessels. Such pulsations have been noted also in the antrum of Highmore and in the marrow canals of bones. After opening the sinus one determines the size of the cavity by means of a sound, and then removes the anterior and possibly part of the inferior wall. The sharp edges of the bone are bevelled off and one tries to make instead of an irregular cavity as flat a surface as possible. The more closely the skin is adapted to the subjacent bone, strictly avoiding the formation of a pouch, the

more rapidly will the healing occur. The mucous membrane is thoroughly removed, the upper part of the ductus nasolacrymalis being also robbed of its mucous membrane. If this is closed it is unnecessary, nay, even harmful, to open it. Formerly when one did not primarily remove the mucous membrane, it was of course necessary to establish a communication with the nose, either by passing a sound through the ductus nasofrontalis or by breaking into the nose, in order to give the secretions an outlet.

If one obliterates the cavity in the above-described manner, however, the ductus nasofrontalis not only becomes superfluous but its artificial opening may do harm by allowing inflammatory products from the nose to come in contact with the wound. The after-treatment is to be in accordance with the ordinary rules of surgery. Even when one has operated in strongly inflamed tissues and cannot sew, there results at worst after this operation a small abscess cavity, the absolute healing of which is but the question of a short time.

MOTHER AND CHILD.

By F. W. EPLEY, M.D.,

NEW RICHMOND, WIS.

Of all the suffering to which human flesh is heir, none perhaps is more acutely painful and distressing than that caused by sore nipples in the act of nursing. How often do we see the young mother writhing with pain and the big tears streaming down her cheeks in her heroic attempts to nourish her offspring—this crowning act of motherhood, this climax of maternal affection turned into tortures akin to those of the Inquisition. If we look for the cause we shall not have to search long. Improper habits of dress have cramped the glands and embedded the nipples within them, or if begun early enough have prevented the development of the nipple, so that if any have grown they are distorted and retracted out of all semblance to the proper shape and figure. This in turn has cramped and distorted the larger milk tubes leading to the nipple, until when lactation takes place it is nearly or quite impossible for the infant to get hold of it, and if it does the result is that the folds of inverted skin are drawn out, the accumulations of skin cells are easily displaced, leaving only the most delicate layer of true skin to withstand the irritation and violence of the nursing act. This it is wholly unable to do, and the result is that in the drawing out of the nipple the skin is fissured. The crack becomes deeper and deeper, nursing more and more painful, until the poor mother gives up in despair. By this time infection has taken place, or by reason of the distorted milk ducts the proper discharge of the lacteal fluid has been impossible, and mastitis and abscess with all their painful sequelæ supervene.

The remedy is just simple, plain common sense, but this must be applied before confinement; it is too late after lactation has actually begun. Let us see what we have two months before the end of gestation: a small, stunted, deformed, retracted, very tender nipple—exactly what we do not want in any particular. We want for baby's use a large, long—I never saw one too long—well formed, protruding, tough-skinned nipple. Can we make it? We can, by exactly the same process by which any part of the body may be developed and toughened, namely, by frequent regular exposure, use, and irritation. At the end of the seventh month the nipples should both be subjected to a systematic course of massage, pulling, rubbing, rolling and stripping, and especially the latter. This cannot be done too often or too thoroughly. The result will be most gratifying. The otherwise wholly useless and worse than useless organ will be prepared for its work; lactation will be free and painless. The glands will be well and easily emptied; the nightmare of fissures, mastitis, and abscess will disappear never to return, and the young mother can hug her baby to her breast and say how sweet is maternity.

In my early years of practice I have experienced all the evils of neglect and mismanagement of the maternal font, until, driven to desperation almost by my repeated failures to relieve this most distressing condition, it occurred to me to put into practice this simple common-sense plan of preparation, and I have had the extreme gratification of seeing all my patients so treated go through lactation with only sensations of pleasure.

My only defence for the principles embodied in this paper is that they are based on observation in an active practice of general medicine, extending over a period of twenty years, and the rearing of a family of five children, who are almost never ill.

When a baby presents himself for admittance into the family circle he should receive a warm welcome. The temperature of the welcome should be maintained until the little fellow is able to kick and jump with sufficient vigor to maintain a healthy circulation. If he is strong and vigorous he should have one good general bath, after that he should be kept simply clean. The common practice of giving the poor little creature a daily scrub all over with soap and water is to be discouraged. Soiled or wet linens should never be allowed to remain in contact with the delicate skin, and when changed should be replaced with warm, soft, clean ones. The eyes should be kept clean, but never washed with the same cloth used for the general bath. For this purpose, a clean cloth, clean water, and no soap should be used. Feed regularly, but not oftener than once in two hours. I do not lay this down as an arbitrary rule never to be broken, but it is an important point; the little stomach needs rest, and much can be done toward the fostering of the digestive and assimilative powers by an intelligent observation of this principle. Teach the baby to drink early. Wash his mouth, gums, tongue, and cheeks regularly. If the mother is weak, sick, thin in flesh, or while nursing loses flesh to any marked degree, if the baby does not seem to thrive, or the mother's milk is not sufficient and has to be supplemented by other food after she has resumed her accustomed place in the household, wean the baby. A good healthy cow is far preferable as a commissary department for baby than a mother's breast which is wanting in any essential quality. I did not read this in a book or hear it in a lecture room. In the selection of a cow great care should be taken to get one free from disease. She should be tested by a veterinary for tuberculosis; kept in clean, dry quarters, fed regularly on clean hay and bran, and in winter given water slightly warmed to drink. If she becomes heated, worried, or excited in any way unduly, the milk should be suspended and some preparation containing milk as a basis should be used until the cow regains her normal condition. Use simple nipples pulled over the mouth of the bottle. Teach baby to drink as soon as possible and discard the bottle altogether. For the first year only soft woollen fabric should come in contact with the skin, and there should be plenty of outer clothing to keep the body warm. It is true infants have great powers of resistance, but it is a fact that many a baby has been buried because the mother has been overzealous to have her baby look prettier than her neighbor's; has changed the wool fabrics for light white goods. She has not realized the chilly air as evening approached, has put the little one to bed in its cotton underclothes or nightdress; the baby during the night has become

chilled and a fatal cholera infantum or enterocolitis has been set up. No matter how warm the night the bowels should be covered with flannels. At home is the place for the baby under all circumstances and conditions. There is no exception to this rule, especially during the heated summer months; new faces, strange surroundings, and the fatigue of travel are prolific sources of indigestion and its natural train of evils. It is these and the natural strain upon the delicate nervous system incident to them, and not the change of food, which make baby sick.

SOME THOUGHTS ON TEACHING ANATOMY.

BY J. W. HENSON, M.D.

THE times demand that graduates in medicine should be better prepared. Requiring a high percentage upon examination is a good thing. It is one means to gain the end, but it is insufficient. To pass creditably a pretty rigid examination is not always a proof of proficiency. What then? It behooves us as teachers to make our course of instruction more thorough and attractive. I use the latter word advisedly, for, unless made attractive, teaching can scarcely be thorough. How shall we accomplish this in anatomy? Every one will subscribe to the statement that impressions made upon the brain through the medium of sight are far more lasting than others.

What is told us we forget, however exciting the narrative may be. What we see our memory retains almost indefinitely, even the details. Anatomists believe this, as shown by the importance attached to dissecting. If this same principle, viz., appealing to the sense of sight, be applied to our preparation of men for dissecting, our teaching will be both attractive and thorough. So much is expected of the dissecting-hall that students are not properly prepared to enter it, and as a result do poor dissecting and, worse still, learn not half so much from what is seen there as they should. Therefore let us make more use of diagrams, preserved dissections, and models, models of viscera and regions, each made to take apart and show the interior of a viscus or the relations of all the structures of a region. Often after the use of the roughest diagram students will report that the point is for the first time made clear. Accentuation is the secret of this success. The same thing obtains in the use of models. The parts in a dissection may seem all confusion to the mind of a beginner, while the clear outlines, the very boldness of a model will appeal to the mind of the dullest. The study of relations is greatly facilitated, not only by this same accentuation, but by the ability to remove the parts layer by layer or piece by piece and replace at will. Upon one occasion a class was for the first time listening to a general description of the cerebrum—the surfaces of the hemispheres, longitudinal fissure, etc. Several brains just taken from cadavers and in good condition were distributed. In spite of this a blank expression, almost universal, greeted the remarks. In desperation, the cerebrum was compared to the half of the kernel of a walnut. Instantly the light of comprehension appeared upon the faces of the men and the description was then easy. This occurrence only illustrates a constant experience which proves the following: First, that the mind of a beginner is usually slow to understand well a demonstration upon some part of the human subject. Secondly, that the same facts are quickly and clearly comprehended when some simple but homely imitation is used to illustrate. Thirdly, that upon the mind prepared by some such rough illustration a demonstration upon the cadaver makes lasting impression. Properly prepared and preserved, dissections can be made almost as useful as models, the several structures being brought out by coloring. Of every region there should be several dissections, each showing a separate layer—thus relations can be clearly observed. Viscera can be hardened carefully, cut in pieces (so that every part of the interior may be demonstrated), the necessary coloring done, and each piece varnished. The result is highly satisfactory.

Progress of Medical Science.

Rupture of Interstitial Tubal Pregnancy; Suture; Recovery.—A case is reported by Tytler in the *British Medical Journal*, June 12, 1897, of a woman, thirty-one years old, who had borne seven children, and came under observation in a state of collapse from internal hemorrhage. Menstruation had been absent for six weeks, and the woman had been seized with severe pain at the bottom of the abdomen, although after a few hours she arose and resumed her work. The menstrual flow returned after this, but the discharge was dark and scanty. Five days after the onset of the acute attack noted, while washing clothes the woman was again suddenly seized with great pain in the stomach and became as cold as death. She was put to bed, and remained in a state of great collapse for five days. At this time she presented marked pallor, coldness of the surface, feeble pulse, etc. On physical examination of the abdomen a rounded mass was found, softish and smooth, low down and to the right of the middle line. Impulse applied to the cervix was communicated to the tumor. There were mucus and blood in the vagina. The cervix uteri was deeply torn on the left side. The thoracic and other organs were normal. Percussion over the lower part of the abdomen was clear, and nothing could be found in Doulgas' cul-de-sac. For a day or two the patient appeared to rally, but at the end of this time she began to vomit and grew much worse. A small exploratory incision was now made between the pubes and the umbilicus, with a view of verifying the diagnosis of ruptured tubal pregnancy. On opening the peritoneum the abdomen was found to be full of black clotted blood. The incision was at once enlarged and a hand introduced to compress the right broad ligament, to prevent renewed bleeding. There was, however, no sign of recurrence or of recent bleeding. A rent, nearly two inches long, was found in the uterus on the right side, extending from the middle to the origin of the right oviduct. The right side of the fundus was twice the breadth of the left. The rent opened into a spherical cavity filled with fibrin, which was removed, without disclosing, however, any trace of cyst wall or ovum. After clearing the peritoneal cavity, the right tube and ovary were removed. Then after carefully washing out the fundus of the uterus, the rent was closed with four catgut sutures, the edges being inverted slightly. After again carefully clearing out and inspecting the peritoneal cavity, a drainage tube was introduced and the abdomen closed in the ordinary way. The patient made a good recovery and was discharged some six weeks after the operation, with a small sinus at the lower end of the wound at the site of the drainage tube. This sinus remained open for some months, discharging a suture now and again until it healed. About eight months later the patient had a severe attack of dysentery, following which there was more or less diarrhœa at each menstrual period.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, August 7, 1897.

CLINICAL EXPERIENCES WITH TR TUBERCULIN.

THE editor of the *Deutsche medicinische Wochenschrift* has undertaken to secure from various clinical sources reports of the results obtained from the employment of Koch's modified tuberculin in the treatment of different forms of tuberculosis, and presents in the issue of that journal for July 8th two communications upon this subject. The authors of these papers are extremely cautious and conservative in their statements and disclaim any suggestion of committing themselves to final conclusions in the matter, which it is pointed out can be reached only after an experience of months and even of years.

Bussenius reports the results in nineteen cases observed during three months at the clinic of Professor Fraenkel at the Charité for the treatment of diseases of the nose and throat. Of these cases twelve were examples of laryngeal tuberculosis, four instances of lupus, two examples of pulmonary tuberculosis solely, and one was an example of asthmatic attacks. Of the whole number the treatment was completed in fifteen, in one it was intermitted, and in the remainder it was still in course of application. The fifteen cases received in all three hundred and fourteen injections, the remainder twenty. The largest number of injections received by a single patient was twenty-five. The largest single injection consisted of four cubic centimetres. The longest period during which the treatment was continued was sixty-five days, the shortest twenty-nine.

The fifteen cases in which the treatment was carried out to its conclusion yielded no reaction to Koch's old tuberculin. Only four of the cases yielded no reaction whatever, local or general, to the injections. The greatest elevation of temperature in a previously non-febrile case following an injection was 2.7° C. The reaction and its quality differed with the specimen of tuberculin employed. One preparation was capable of inducing a reaction in the same person in whom a larger dose of another preparation at a previous time had induced none. The frequency of pulse and respiration corresponded as a rule with the height of the temperature. Elevation of temperature was attended with evidences of nervous disturbance, such as headache, languor, twitching, palpitation of the heart, which sometimes occurred also independently of such elevation. Two patients complained regularly of oppression of the heart and profuse perspiration. In a series of examinations of the blood no noteworthy alteration in the number of colorless corpuscles was found. In two of the cases reported enlargement of the spleen was made out.

Of the fifteen cases in which the treatment was continued until its completion there was gain in weight in seven, loss of weight in five. Such loss as took place occurred principally in connection with the administration of large doses and violent reaction. In no instance did an abscess form at the site of injection, but in ten of the nineteen painful infiltration of the subcutaneous tissues took place. In two cases the local lymphatic glands became slightly enlarged. In the cases of pulmonary tuberculosis the results were not considered conclusive, but in two in which tuberculosis and syphilis were associated the employment of TR after the cure of the syphilis was followed by the disappearance of cough and expectoration, together with tubercle bacilli. Tuberculosis of the pharynx and larynx showed no greater improvement than is usual with ordinary topical treatment. Three cases of lupus, however, were quite cured.

At the medical clinic of the University of Bonn Schultze treated nine cases of tuberculosis with TR. In none was any such aggravation observed as followed injections of the original tuberculin. In one case tuberculosis of the larynx developed during the progress of the treatment, with loss of weight, and the patient declined to submit to further treatment. In another the treatment was discontinued on account of the development of diarrhœa, probably of tuberculous origin. In this case there was at first gain, but later there was loss of weight. In four other cases there was no noteworthy change. In still another improvement took place in a dry pleurisy and also in the general condition. In the remaining two improvement took place, and in one of these pronounced perichondritis of the arytenoid cartilage was cured.

VACCINATION IN ENGLAND.

IN many districts of England there exists the strongest possible prejudice against vaccination. Nothing can shake the belief of the rabid antivaccinationist that the operation is distinctly harmful; he is not satisfied with disallowing its efficacy. To statistics and proofs of every kind he turns a deaf ear or explains them away to his own satisfaction. He is an enthusiast in the support of his cause, and will pay fines time after time and even go to prison rather than allow his children to be vaccinated. The causes for this decided stand against vaccination are not altogether easy to explain. One reason may be that the present strict enforcement of the law of compulsory vaccination is looked upon as an infringement on the liberty of the subject; ignorance is doubtless another; and lastly the carelessness of many of the public vaccinators is an important factor in the case. The report of the royal commission on vaccination in England and particu-

larly in regard to the late small-pox epidemic in Gloucester has just been published, and should tend to convince disbelievers of the efficacy of Jenner's discovery. The commissioners, one and all, after a careful and unprejudiced consideration of the subject, commit themselves to the opinion: 1. That vaccination diminishes the liability to be attacked by the disease. 2. That it modifies the character of the disease. 3. That the protection it affords against attacks of the disease is greatest in the years immediately succeeding vaccination (say for nine or ten years). 4. That after the lapse of this period the efficacy of vaccination rapidly diminishes, but that it is still considerable in the next quinquennium and probably never altogether ceases. 5. That its power to modify the character of the disease does not diminish so rapidly as its power to prevent attack. 6. That revaccination restores the protection which lapse of time has diminished. 7. That the beneficial effects of vaccination are most experienced by those in whose case it has been most thorough. In Gloucester at the time of the outbreak vaccination had been practically abandoned, and figures show that the disease and mortality were nearly wholly confined to the unvaccinated. The epidemic was soon exterminated when the vaccination machinery had been effectively organized. It is a remarkable fact that there was not a single case of small-pox among the nurses or workers, all of whom had been revaccinated. Estimates which can be relied upon put the yearly death rate from small pox in England during the latter half of the eighteenth century at the proportion of three thousand to every one million of the population; with the present number of inhabitants this would mean one hundred thousand cases a year. In 1890 there were in England only sixteen deaths from small-pox, but since then there has been a most alarming increase. This increase is without a doubt due to the antivaccinationist movement.

The existing laws are very unpopular and possibly an amendment of them might be beneficial, but the demand of the opponents of vaccination that they should be totally repealed would be nothing less than a national calamity.

THE DISUSE OF ERGOT IN PRESENT-DAY MIDWIFERY PRACTICE.

The abuse of ergot has led to so radical a change in the views of medical men as to the useful qualities of that drug in obstetric practice that the other extreme has been reached, and it is now scarcely ever used. The great majority of obstetricians nowadays seem to have arrived at the opinion that the use of ergot is not indicated in any stage of labor, but that after the uterus is completely emptied of its contents it may prove valuable in the prevention of post-partum hemorrhage. Dr. T. More Madden, of Dublin, joins issue with these conclusions, and holds to the view that under many conditions of labor the use of ergot is most beneficial. Dr. Madden's experience has been so extensive that his opinion must carry weight. He says that, as regards the circumstances under which ergot may be employed in midwifery practice, "judging from the recent literature of this subject, it may not be superfluous to premise that to use ergot or any of its preparations safely and effectively during parturition the presentation should as a rule be cranial; that there should be no disproportion between the fœtus and maternal parts, nor any obstacle to a deliverance in the genital tract; that the os uteri, if not previously fully dilated, should at least be sufficiently dilatable to allow speedy delivery by the forceps whenever that may become necessary; and that a preparation of ergot should be selected and a dose given calculated to produce the required ecbolic effect. Under such conditions ergot may be given with utility when required either before, during, or after the second stage of labor, viz.: 1st. In some instances: (*a*) of delay from inertia of the uterus before full dilatation of the dilatable os and in which there is any evident danger to either mother or child from protraction of labor. 2d. It may be administered during the second stage; (*b*) in nearly every case of long delay from inertia wherein the presentation is natural and the delivery not otherwise impeded, or in which (*c*) there is then reason to apprehend either the probability of subsequent hemorrhage or any such complication as may call for its use. 3d. During the last stage of labor this ecbolic may be employed (*d*) to hasten the expulsion of the placenta when delayed by inertia, or (*e*) for the arrest of hemorrhage. 4th. After labor ergot may be resorted to either immediately (*f*) to prevent or check flooding, or subsequently (*g*) to produce such tonic or permanent contraction as will effectually seal up the uterine vessels and so lessen the liability to subsequent septic invasion; or (*h*) to effect the expulsion of clots and so arrest afterpains. 5th and lastly, (*i*) to stimulate such contraction as may quicken or secure the process of involution after parturition." Dr. Madden believes in bold, full, and effective dosages of ergot, and uses the fresh liquid extract of the British Pharmacopœia. The dose he gives is two or three drachms by the mouth and a drachm by deep hypodermic injection in the gluteal region at the same time. The abstract of one hundred and fifty cases in which ergot was used in all stages of labor as well as after the birth of the child are given. In one hundred and forty-eight cases the result was favorable to the mother. The paper concludes with these words: "My experience on this subject points to the conclusion that the dangers which are now so commonly ascribed to the use of ergot in obstetrics are probably largely attributable to its misuse, or administration in unsuitable cases, or in insufficient doses, and therefore furnish no argument whatever against its judicious and proper employment."

En Route to Moscow.—The *Normannia*, which was prevented from sailing on July 29th through the discovery of a crack in one of her crank-shaft journals, had on board thirty physicians from Mexico who were bound for Moscow. They sailed two days later on another vessel.

News of the Week.

Dr. Charles G. Duncan, of Socorro, N. Mex., has been appointed delegate from the New Mexico Medical Society to the Montreal meeting of the British Medical Association.

Medical Schools in Denver.—The supreme court of the State of Colorado has forbidden the University of Colorado from carrying on any part of its medical department in Denver, because the constitution locates the university itself at Boulder. In consequence of this the members of the faculty resident in Denver have resigned, and most of them have united with the medical department of the University of Denver. Among those who have thus strengthened the Denver Medical School are Dr. H. T. Pershing in diseases of the mind and nervous system, Drs. S. G. Bonney and H. B. Whitney in medicine, Dr. Charles A. Powers in Surgery, Dr. Walter A. Jayne in gynæcology, Dr. George B. Packard in orthopædics, Drs. L. E. Lemen and J. W. O'Connor in clinical surgery, Dr. T. E. Taylor in clinical obstetrics, and Dr. John Chase in clinical ophthalmology. The faculty of the school has been further enlarged by the election of Dr. P. V. Carlin in obstetrics, Drs. W. H. Bergtold and W. B. Fenn in pathology, and Dr. Carroll E. Edson in therapeutics.

The Results of the Pennsylvania State Medical Examinations.—Of four hundred and forty-five applicants for license to practise medicine examined by the Pennsylvania State board in June of this year eighty-three failed to pass a percentage of 18.56. The whole number included twenty women, of whom seven failed to pass. The examinations were said to have been a little more rigorous than in previous years. In a spirit of equity the papers of those that failed were examined a second time by the board.

A Hospital without a Site.—The governor of Pennsylvania has felt constrained to veto an appropriation for $10,000 for the American Hospital Association of Mahanoy Township, Schuylkill County, for maintenance for the fiscal year beginning June 1, 1898, because the association is yet without a hospital building and without a site for the erection of one.

Lehigh Valley (Pa.) Medical Association.—The seventeenth annual meeting of the Lehigh Valley Medical Association was held at Water Gap, Pa., on July 28th and 29th. Dr. L. Duncan Bulkley, of New York, delivered an address on "The Importance of Little Things in Dermatology." Dr. Mary Greenwald, of Stroudsburg, was elected *President;* Drs. Howell, of Wilkesbarre, Wilson, of Bethlehem, Mensch, of Montgomery County, and W. C. Albertson, of Belvidere, *Vice-Presidents;* Dr. Charles McIntire, of Easton, *Secretary;* Dr. W. S. Stewart, of Wilkesbarre, *Assistant Secretary;* Dr. A. Stout, of Bethlehem, *Treasurer.*

The Indian Territory Medical Association.—At the regular semiannual meeting of this association, held at South McAlester, I. T., June 29 and 30, 1897, the following officers were elected for the ensuing year: *President,* Dr. E. N. Allen, South McAlester, I. T.; *First Vice-President,* Dr. G. W. West, Eufala, I. T.; *Second Vice-President,* Dr. J. B. Roleter, Oklohoma City, O. T.; *Secretary,* Dr. LeRoy Long, Caddo, I. T. The next meeting of the association will be held at Muskogee, I. T., December 7 and 8, 1897.

An Alumni Association of the German Hospital in this city has been organized with the following officers: *President,* William K. Kubin; *Vice-President,* Franz Torek; *Treasurer,* Alexis V. Moschcowitz; *Recording Secretary,* Selian Neuhof; *Corresponding Secretary,* Gustav G. Fischlowitz. The association will hold semiannual meetings in April and November of each year.

The International Congress.—Drs. Danilevski, of Kharkov, and Frédéricq, of Liége, will not deliver addresses at the general meetings. In place of them Dr. Metschnikoff will deliver an address on "The Plague," and Dr. Lannelongue one on "The General Treatment of Surgical Tuberculosis." There is some complaint, apparently well founded, of dilatoriness on the part of the management of the congress. No information concerning hotel accommodation, transportation, etc., was given out until it was too late for many living at a distance from Moscow to profit by it. The offer of free railway tickets in Russia is very liberal, but as it applies only to those who have cards of membership, several from this country who have sent their subscription but received neither membership card nor receipt are unable to avail themselves of the offer.

Substantial Recognition of Dr. Sanarelli's Services.—The Uruguay legislature has conferred honorary citizenship upon the discoverer of the yellow-fever microbe, and has also voted him a donation of ten thousand dollars, at the same time recording its regret that "the unhappy condition of the country does not admit of its doing more to evince its gratitude to a physician and naturalist who has already laid those regions under so many obligations."

News for New Yorkers.—The heat-wave that has recently rolled over the United States now happily shows signs of abatement. Since the first of this month, however, about two thousand cases of severe prostration and three hundred and fifty deaths due to the excessive heat have been reported in New York alone. The deathrate in other parts of the States has registered a corresponding increase. It looks as if the elements have chosen that part of North America as their special arena when they want to "run amuck."—*Medical Press and Circular,* July 14, 1897.

Burned by Roentgen Rays.—The daily papers report a case of extensive burning by *x*-rays in the person of a young woman who was skiagraphed in order to determine the nature of a supposed affection of the antrum of Highmore. It is stated that all the hair has fallen from one side of her head and that the skin of the face and neck was also blistered over a large surface.

A Hospital Quarrel.—Owing to differences which have arisen between the medical board and one of the consulting surgeons of the Bayonne Hospital, it is reported that the board of managers has removed the entire consulting staff. It is understood, however, that all will be reappointed with the exception of the one member whose action in a certain case was the cause of the dissension.

Malaria Following Flood.—It is reported that malaria prevails to an unusual degree along the Mississippi lowlands which were flooded by the high water last spring. When the flood receded many lakes and pools of stagnant water remained, and to the presence of these is attributed the increase in the prevalence and mortality of the disease.

An Unpleasant Interruption to an Excursion.—Twenty-seven American tourists are on board of the steamer *Passport* in Toronto Bay in quarantine. They arrived there from Montreal on August 1st and intended to leave by train for their homes the same day, but the medical health officer at Toronto met the steamer with a tug and informed the captain that there was a small-pox case on board and that the passengers and crew would have to remain in quarantine twelve days. The man who was the cause of the detention had been under observation at Belleville, but escaped and boarded the steamer when she touched there.

The Water Supply of Boston.—The State of Massachusetts has undertaken to supply the metropolitan water district, including Boston and twenty-seven other towns and cities, with pure water from an immense lake, nine miles in length, covering forty-one hundred and ninety-five acres, three hundred and eighty-five feet above high-water mark, and with an average depth of forty-six feet. It is to take the place of what is now a busy manufacturing district in the valley of the upper Nashua River. The greater part of two towns and five villages, including churches, schools, the houses of seventeen hundred and eleven people, two large mills, and hundreds of small farms will be wiped out of existence to provide for this enormous reservoir. Its construction made necessary the passage of a law, said to be without a precedent in this country, which provides that the State shall pay to such employees of the mills at the time of the confiscation of the property a sum equal to six months' wages. The State also treats liberally people with established businesses, the value of which the seizure of land for reservoir uses completely destroyed, by a liberal allowance for accumulative or prospective damages. When all this is done, the people of Massachusetts will have a bill variously estimated at from $30,000,000 to $50,000,000 to pay.—*The Sanitary Era.*

Suicide a la Parisienne.—Four seamstresses in Paris recently decided that life was not worth while, and perhaps they had cause to be tired of it, for the husband of the eldest, who was but twenty-five years old, was insane, another had been deserted by her husband, the third had been jilted by her lover, while the youngest, aged seventeen years, joined the others out of sympathy. They dined together one day and then passed a jolly evening, drinking cherry brandy. When the bottle was empty they signed a statement to the effect that they died with pleasure, closed the door and windows tightly, and then lighted a charcoal fire, the fumes of which killed them. One of the women was the great-grandniece of a former archbishop of Paris, who was executed during the reign of terror.

Obituary Notes.—Dr. John Joseph Curran, of this city, died two weeks ago of heart disease. He was thirty-seven years old and was born in Newport, R. I. After graduation from St. Francis Xavier's College, he studied medicine at the College of Physicians and Surgeons, where he received his degree of M.D. in 1888.—Dr. E. M. Ike, of Altoona, Pa., died on July 29th as a result of a laceration of the hand by a broken bottle. He was born March 21, 1867, and was graduated from Jefferson Medical College in 1888.

Results of a Tank Inspection.—The special inspection of water tanks in tenement houses ordered by the board of health last month has resulted in the discovery that 1,343 out of 6,060 tanks examined were in an improper condition. The board has ordered the owners of the buildings in which the unhealthy tanks were found to cleanse them forthwith.

The St. Louis "Smoker."—In a recent issue we published a charge made by the *Medical Fortnightly* that a "smoker" held recently at St. Louis degenerated into such disgusting story telling that several of the invited guests were compelled to leave the room. As a matter of fair play we also inserted a refutation of the charge, glad of the opportunity to do so without any expression of opinion on our part. Since then we have received a letter from Dr. Norbury, editor of the *Fortnightly*, reiterating the charges, and from his standpoint substantiating them on the testimony of several gentlemen who were present. We mention these facts in order to say that we hardly think it worth while to discuss the subject further, being willing to give any benefit of doubt on the side of a charitable construction of the difference of opinion, thus impliedly holding up the decency and dignity of the profession as a whole. We cannot see that anything more can come of this by further discussion of the pros and cons.

The Rocky Mountain Interstate Medical Association.—This is an organization of the regular medical profession of Colorado, Utah, Montana, Idaho, Wyoming, New Mexico, and Arizona. The idea of this society was formulated by Drs. C. K. Fleming, J. W. Hull, Leonard Freeman, and Robert Levy, of Denver, Col., in the summer of 1896. A circular letter was sent by them to prominent physicians inviting their opinion as to the desirability of such a society and their co-operation in its organization. The plan received the hearty and almost universal approval of individual physicians as well as the indorsement of the Colorado, Utah, and Montana State medical societies. Accordingly a committee of three, from each of these seven States, was appointed to draft a constitution and

bylaws and to organize the society. This committee met at the Knutsford Hotel in Salt Lake City, July 24, 1897, with the following members present, viz.: Colorado: Drs. C. K. Fleming, Clayton Parkhill, and D. H. Coover, of Denver. Utah: Drs. C. P. Hough, C. G. Plummer, and A. S. Bower, of Salt Lake City. Montana: Drs. C. K. Cole, of Helena; Henry Chapple, of Billing, and T. J. Murray, of Butte City. Wyoming: Dr. E. Stuver, of Rawlins. The committee organized by electing C. P. Hough president, and E. Stuver secretary, and at once proceeded to the consideration and adoption of a constitution and bylaws. The code of ethics of the American Medical Association was adopted. The following officers were elected for the ensuing year, viz.: Charles P. Hough, *President*, Salt Lake City; C. K. Cole, *First Vice-President*, Helena, Mont.; Clayton Parkhill, *Second Vice-President*, Denver, Col.; E. Stuver, *Secretary* and *Treasurer*, Rawlins, Wyo. It was decided to hold the first annual meeting in Denver, in June, 1898, during the meeting of the American Medical Association.

Death and Honorary Distinction.—M. Caplat, director of the Departmental Asylum of Nanterre, in France, who received the cross of the Legion of Honor on the occasion of a visit paid to that place by President Faure, died the following day from excessive joy. A knighthood of the same order also proved fatal to an architect of the Assistance Publique.

Inflammable Hair Wash.—A woman in London died recently from burns received through the ignition of a petroleum hairwash which was being applied to her head by a hairdresser. There was no open flame near her at the time, and the explanation given of the accident is that the inflammable material was set fire to by an electric spark produced by the friction of the barber's hand on the hair.

Navy Department, Bureau of Medicine and Surgery, Washington, D. C.—Changes in the medical corps of the United States navy for the week ending July 21, 1897. July 27th.—Passed Assistant Surgeon S. S. White ordered to report on the *Concord* immediately. July 28th.—Surgeon J. D. Gatewood ordered to Brussels, Belgium, and Berlin, Germany, as delegate, then to return. July 29th.—Assistant Surgeon J. C. Thompson ordered to the naval laboratory, New York. Surgeon H. E. Ames, when detached from the *Cincinnati*, ordered home and granted two months' leave. Surgeon J. E. Gardner detached from the *Amphitrite* and ordered to the *Dolphin*. Surgeon F. Anderson detached from the *Dolphin* and ordered to the hospital, Yokohama, per steamer of August 14th. Surgeon H. G. Beyer detached from Museum of Hygiene and ordered to the *Amphitrite*. July 30th.—Passed Assistant Surgeon T. B. Bailey detached from the *Machias* and ordered to the *Yorktown*. Passed Assistant Surgeon J. S. Page detached from the *Yorktown* and ordered to the *Olympia*. Passed Assistant Surgeon G. Rothganger detached from the *Pinta* and ordered to the *Wheeling* August 10th. Passed Assistant Surgeon M. R. Pigott detached from the *Olympia* and ordered to the *Machias*.

Obituary.

JOHN J. H. LOVE, M.D.

Dr. John J. H. Love died suddenly on the morning of July 30th, while at the bedside of a patient. Up to the moment that he was stricken he had apparently been in the enjoyment of perfect health.

Dr. Love was born in Harmony Township, N. J., on April 3, 1833. He was educated at Lafayette College, subsequently taking his medical course at the New York University Medical School, where he obtained his degree of M.D. in 1855. He at once began practice in Montclair. At the breaking out of the civil war he enlisted, serving as surgeon to the thirteenth New Jersey volunteers, and later in the twelfth corps of the army of the Potomac. At the close of the year 1864 he received an honorable discharge and returned to Montclair, where he resided continuously up to the time of his death. He was always prominently identified with the interests of Montclair, which was but a comparatively small village when he first went there to live, although he never held any public office except that of school commissioner. It was in great measure to his labors that the present public-school system of Montclair owed its existence, and he was always occupied in some capacity with its management, first as trustee and later, under the changed system, as commissioner. He was one of the organizers of Trinity Church in Montclair and was on its board of trustees. He was also active in the establishment of the Young Men's Christian Association and in the foundation of a public library. He was a founder of the Montclair Club and of the Bank of Montclair, was a member of the Loyal Legion, of the Grand Army of the Republic, and of many medical societies.

On Tuesday, April 16, 1895, a banquet was given to Dr. Love in the Montclair clubhouse, on the fortieth anniversary of his coming to the town to practise, in recognition of his services to the community. Over two hundred guests, laymen and physicians of Montclair and neighboring places, were present. Congratulatory addresses were made by Mr. John H. Wilson, who presided, and by Messrs. Philip Doremus, Edwin B. Goodell, John R. Howard, Starr J. Murphy, Dr. George F. Shrady, Hon. Franklin Murphy, and the Rev. Dr. A. H. Bradford.

Dr. Love was a man who did his duty and more than his duty in every station in which he was placed, whether as a soldier, a public-spirited citizen, a man of family, or a physician. His many acts of kindness and of unostentatious charity endeared him to all his patients, and his sterling qualities as a man and a citizen raised up for him a host of friends and admirers such as it is given to few men to possess.

The funeral services were held on Monday afternoon, not in the church which he attended, but in the Congregational Church, that being selected because it was the largest in the town, yet numbers were unable to gain admission. The services were conducted by the Rev. Orville Reed, pastor of Trinity Church. Among the pallbearers were Joseph Van Vleck, John R. Howard, Philip Doremus, John R. Livermore, and the medical staff of the Mountainside Hospital, Drs. Whitehorne, Brown, Halsey, Case, Francis, and Newton. Delegations were present in the church from the veterans of the thirteenth New Jersey volunteers, the Loyal Legion, the Grand Army of the Republic, and from the various business, social, and medical associations with which Dr. Love was identified. Dr. Love's wife, son, and two daughters survive him.

Clinical Department.

A CASE OF MIGRATORY PNEUMONIA IN A PARTURIENT WOMAN.

BY H. P. RITCHIE, M.D.,

[illegible], MISS.

THE following is a brief report of a case of lobar pneumonia, which is of exceptional interest because of its unusual course, extreme severity, and happy termination.

Mrs. B——, aged thirty, seamstress, family and personal health record negative, was delivered by me, on September 19, 1896, of her fourth child, after a perfectly normal labor, from which she made a rapid and uneventful recovery.

On October 11th she first ventured from the house, and some hours after her return was seized with a pronounced chill and severe pain in the right lower thorax. The onset was marked and sudden, she being engaged at that time in her ordinary household duties and having no premonition of the attack. Five hours after the onset her temperature was 103° F.; pulse, 110; respiration, 28, accompanied by severe pain. The classical signs of consolidation soon manifested themselves in the right lower lobe, and the case appeared to be one of frank lobar pneumonia.

When she was seen on the third day a friction murmur was present over the extreme right base, and with a small area of movable flatness determining the presence of a complicating pleurisy with a small effusion.

During the night of the 16th the crisis occurred, and when she was seen on the morning of the 17th her temperature was 98.4° F.; pulse, 96; respiration easy, and patient comfortable. Strict instructions as to rest in bed were given and wholly disregarded by the patient, and on the evening of the same day I was called to find the patient just recovering from a severe chill, with dyspnœa, pain in both apices, temperature of 103° F., and pulse of 140.

The next day Dr. Charles L. Greene kindly saw the case with me, and involvement of both apices was suspected and later confirmed by unmistakable signs of consolidation. The middle lobe, however, remained free from consolidation, although the breath sounds were much exaggerated. The percussion note, however, was hyperresonant, and the changes in the pitch in the descent from the dull note of the apex to the hyperresonance of the middle lobe, and thence to the duller note of the consolidated but resolving lower right lobe anteriorly, and to the flat note over the fluid in the back, were very marked. Thus at this time the act of respiration was carried by the right middle and left lower lobes.

On October 20th there was increased expectoration; large râles appeared anteriorly in the right lower lobe, while the note posteriorly was obtained over a smaller area. Both apices presented most pronounced and typical signs of consolidation; accentuation of pulmonary second sound remained well marked.

On October 21st, right lobe resolving, no change in apices. Temperature, 102° F.; respiration, 35; pulse, 118. Widal's test for typhoid fever was tried, with negative results.

This condition continued until October 25th, when the temperature dropped to 100.4° F.; with respiration, 26; pulse, 96 and strong. Breathing was easy and there was profuse expectoration of rusty sputum. Râles of resolution had appeared over the upper lobes, and the patient was very comfortable. The temperature, however, continued to run irregularly from 100 to 102° F. for several days.

On October 29th, the eighteenth day of her illness, I was again called, to find the patient in chill and complaining of intense pain in the left lower lobe. Dyspnœa was extreme and cyanosis marked.

On the morning of the 30th Dr. Greene was again consulted, and consolidation of the left lower lobe was determined. Temperature mounted to 104° F.; pulse, 146; panting. The pulmonary second sound was for the first time very weak, the closure of the valve imperfect, and the patient seemed to be almost *in articulo mortis*. Fortunately the right lower lobe was in its twelfth day of resolution and the apices were in their fourth day, but at the best there must have been but little function. Yet the laboring heart responded grandly to stimulation, and upon November 2d, the third day, the temperature fell to 101° F., with pulse of 107, and respiration of 28, deeper and easier. The fever ran from 100° to 102° F. during the next week, but gradually came to normal, and at the end of the next four weeks the lungs had practically cleared up.

On November 12th signs of inflammation of the right saphenous vein occurred, which condition progressed to a pronounced phlebitis, which kept the patient in bed for six weeks.

Until January 2d I heard nothing further of the case. Then I was called, to find her in a semiconscious condition, with a partial paralysis of the left side. This condition persisted for several hours and passed away, leaving only a slight impairment of sensation, which returned, however, in a short time.

My patient, therefore, suffered from three distinct and successive attacks of lobar pneumonia, involving in turn the right lower lobe, both apices, and the left lower lobe, with an accompanying pleurisy with small effusion on the right side, and had as sequelæ phlebitis and a transitory paralysis, probably due to embolus.

The unusual clinical features make the case one of exceptional interest.

A CASE OF DOUBLE PULMONIC MURMUR, WITH DIASTOLIC THRILL.

BY J. N. HALL, M.D.,

DENVER, COL.,

PROFESSOR OF THEORY AND CLINICAL MEDICINE IN THE UNIVERSITY OF COLORADO.

WELL-MARKED disease of the pulmonary valves in adult life is sufficiently infrequent to make the following case worthy of record:

Mrs. R. M——, twenty-four years of age, with no family history of importance in this connection, presented herself at the medical clinic of the University of Colorado six months ago. She had one healthy child, twelve months of age; no other labors. Although subject to severe attacks of bronchitis for some years, especially in winter, her babyhood and childhood, with the exception of whooping-cough, were apparently free from serious disease. There was no history of rheumatism.

She complained of cough, expectoration, and dyspnœa, and presented high temperature and rapid pulse, with moderate dulness and moist râles in both bases, especially behind. I examined the heart, with negative result. The patient was sent to her home and treated by Miss C. L. Moore, a senior student, she reporting to me upon the progress of the case, which I did not see again. Although the dyspnœa was very marked, recovery ensued after a febrile course of about ten days. The case, although not typical, was regarded as one of pneumonia. Miss Moore examined the entire chest frequently during the illness, without noting anything unusual in the heart's action.

One month ago the patient applied for treatment for

a severe bronchitis, sonorous and sibilant râles being heard through the clothing with the unaided ear by the student detailed to the case. In verifying the student's report, I heard, in addition to the râles mentioned, a very loud and unusual murmur over the heart. The chest having been stripped to complete the examination, the following conditions were noted:

The patient was well developed, of natural color, with the exception of slight anæmia, and presented no œdema, lividity, or clubbing of the fingers. Weight, one hundred and thirty-five pounds. Temperature, normal; pulse, 100; respiration, 34 in a state of rest, but increasing in frequency upon slight exertion. Abundant rough, sonorous, and sibilant râles throughout the chest, without perceptible dulness. Cardiac dulness increased moderately upward and to the right, and nearly to the nipple line to the left. Apex beat just within this line in the fifth space. Valvular sounds of heart normal, excepting over the pulmonic region.

Here there was heard a very loud, whizzing, humming murmur, continuous, but accentuated at the beginning of systole, and changing in timbre at the time of occurrence of the normal second sound, which sound, however, could not be made out over the pulmonic area. The murmur, after the change of timbre noted, continued, louder than before, until the next systole. There was not the perfectly distinct intermission between the two parts of this murmur heard in double murmurs at the aortic and the mitral valves. The systolic portion of this murmur was transmitted much less distinctly, especially downward, over the precordial area, than the diastolic, but was heard with great distinctness between the left scapula and the spinal column, where the diastolic murmur was inaudible. The diastolic portion of the murmur was transmitted most strongly downward, especially toward the apex, but was heard quite distinctly over the entire precordia. Over the second interspace, covering an area of about the size of a silver dollar, was a purring thrill, very distinctly diastolic and occupying the entire diastole.

The bronchitis disappeared after about two weeks, and the patient was exhibited at the meeting of the Denver and Arapahoe Medical Society, March 23, 1897. She was examined by many members of the society, and there was no dissent as to the presence of the signs described, although some discussion occurred as to their interpretation.

My own theory as to the origin of the disease and the interpretation of the signs is as follows, viz.: that she suffered for years previously, possibly from birth, from some defect in the pulmonary valve not giving rise to distinct physical signs. The frequent and severe attacks of bronchitis furnish ground for such a suspicion. The attack of pneumonia, a disease which is prone, as we know, to light up an endocarditis, may well have caused a sudden increase in such a valvular trouble if of endocarditic nature, or may have originated an endocarditis *de novo* upon a congenitally deformed valve. At least, the rapid development of the physical signs since the pneumonia would certainly lead one to connect this disease with the valvular trouble.

The systolic portion of the murmur, rough and transmitted into the back, leads me to infer a narrowing of the pulmonic orifice, while the diastolic portion, with distinct thrill, leaves no room for doubt, I believe, as to the existence of pulmonic insufficiency.

The only case comparable to this one which has come under my observation I saw but once, the woman suffering at the time from an attack of colic. She was thirty years of age, and had experienced, ten years previously, a very severe attack of measles. Three months before she had nearly died from an attack of puerperal fever following an instrumental labor; and she also gave a history of a mild attack of acute rheumatism. So far as the organs within the chest were concerned, she complained only of palpitation and dyspnœa upon exertion.

The area of cardiac dulness was slightly enlarged, and she presented the following murmurs, without thrill, viz.:

(*a*) An apical systolic murmur, transmitted into the axilla, having the usual characteristics of the murmur of mitral regurgitation.

(*b*) A diastolic murmur, heard most distinctly over the aortic area, transmitted toward the lower end of the sternum and slightly to the left, prolonged, and rather rough in character.

(*c*) A diastolic murmur, soft and blowing, most distinct at the second left interspace, of different timbre from the one to the right of the sternum, transmitted directly downward to the fourth rib.

Between the locations of the two last-described murmurs was a space where neither could be heard distinctly. I do not feel, however, in the absence of thrill, in the presence of well-defined aortic regurgitation, and especially in view of the known rarity of the affection, that one could speak positively of pulmonic regurgitation in this case, although I believe it existed. I considered it possibly of septic origin.

In the first case, Dr. Charles Denison suggested the possibility of pressure upon the pulmonary artery by tuberculous deposit in the lung, or by tuberculous glands. In a careful examination since the recovery from the bronchitis, I was unable to find any evidence, rational or physical, of such a condition.

VAGINAL HYSTERO-SALPINGO-OÖPHORECTOMY BY ENUCLEATION, WITH THE INDIVIDUAL LIGATION OF VESSELS ONLY, FOR PUERPERAL METRITIS, INTRAMURAL ABSCESS, ETC.

By J. COFFIN STINSON, M.D.,

THE following case is reported rather fully, as it presented several points of interest:

Mrs. M. L——, aged thirty-three years; three children living; always enjoyed fairly good health; had two miscarriages; from the second she made a slow recovery, being confined to her bed for three months.

The patient was first seen by me March 19, 1897, in consultation with Dr. N. Selling. For six weeks previous to the time Dr. Selling was called to the case, the patient had a persistent flow, due probably to a partly detached placenta. The physician who previously had charge of the case had for some weeks endeavored by rest, vaginal packings, etc., to carry the patient through her period of gestation. When she was first seen by Dr. Selling, her general condition was very poor. She was in a fainting condition bordering on collapse, exceedingly anæmic, and had vomiting, headache, and intense thirst; rhythmical uterine pains were accompanied by alarming gushes of blood. Pulse was 140; temperature, 101° F. (mouth); abdomen tender; fundus at about the height of six months' pregnancy; os dilated, admitting a finger, which detected, after removing a large quantity of clots, a portion of detached placenta above the internal os.

I saw the case with Dr. Selling three hours later, and on account of the urgent condition I delivered that same afternoon as soon as preparations could be made. She was placed in the lithotomy position, the os was manually dilated, the membranes were ruptured, a foot was grasped, the fœtus delivered, and placenta removed. There was a very foul odor from the fœtus, etc.,

during extraction. The uterus was lightly curetted and irrigated with bichloride solution, followed with boiled water. The patient was in such poor condition that no anæsthetic could be administered. She vomited the stimulants given her during the operation. She was given saline and stimulating enemata, and rectal feeding was also resorted to for several days. The uterus was subsequently irrigated twice daily. She was given stimulants, tonics, and later some solid food, as soon as her stomach could retain it. The temperature gradually rose from 101° F. (one-half a degree each day) till it reached 103° F., when the uterus was curetted, irrigated, and carbolic acid applied. The temperature gradually dropped to 101° F., when she had a chill and the temperature rose to 104° F. She now complained of pain and tenderness in the left inguinal region. She was again curetted and irrigated with bichloride and peroxide solutions. The temperature dropped by lysis to 100° F., and in a few days to 98.8° F., where it remained for several days. Pulse varied now from 100 to 105. On the afternoon of April 11th she had a slight chill followed by a rise of temperature to 102° F., and complained of pain on the left side above the pubes. Examination showed thickening and tenderness of the left tube and ovary, also some tenderness on the right side. The temperature ran along between 101° and 102° F. for several days, but on the evening of April 16th it reached 103.2° F. Her general condition was now poor. Thinking that the woman might be saved by radical measures, preparations were made for operation, which I performed the following morning at eight o'clock. The morning temperature was 101° F.; pulse, 110. Chloroform was administered by the drop method. The patient was placed in the lithotomy position, with the pelvis slightly elevated (Edebohls' table). The uterus, tubes, and ovaries were removed per vaginam by enucleation, with the individual ligation of vessels only. The enucleation, which was somewhat difficult on account of the size and friability of the uterus, was facilitated by using "long forceps as temporary hæmostatics, levers, and tractors"—what I call "an addition to the enucleation method." Long forceps were clamped successively on the broad ligaments close to the uterus, while the latter was from time to time separated from the former by blunt dissection aided at times by cuts from the scalpel, keeping very close to the uterus. By making slight traction on the severed portions of the broad ligaments, using the forceps as levers and tractors, the cut edges could be brought well into view so as to inspect the stumps for open mouths of vessels, which were clamped with small forceps and ligated with fine catgut. Then the long clamps were removed, but small forceps were first applied at the upper angles of the pedicles, to control them so that the stumps could be again inspected before the gauze packing was introduced, when the forceps were removed. Under such circumstances the clamps are an addition to the enucleation method, acting temporarily as levers and tractors, and as prophylactics against hemorrhage, while the severed portions of the broad ligaments are inspected and the vessels located and ligated. Three arteries were ligated during the operation. After the removal of the uterus and appendages, a portion of the intestines, which presented evidence of diminishing peritonitis, was freely irrigated with hot saline solution and then dried with sponges. The pelvis, the cut edges of the broad ligaments, and vagina were lightly but systematically packed with wide strips of bichloride gauze (moist). Finally an occlusion pad of the same gauze and a T-binder were applied.

Description of Specimen Removed.—The specimen was about the size of a uterus between the third and fourth months of gestation, showing that it had undergone a considerable degree of involution. The walls were markedly friable, there was an abscess in the left wall near the fundus, the left tube (which was severed during the operation, allowing the escape of pus) contained pus. On pressure pus exuded from the left cornu of the uterus (a tubo-uterine abscess). The left ovary was of the size of a hen's egg, solid, and contained a small abscess on its surface where it had been connected with the tube; the right tube and ovary were injected but not enlarged.

Treatment and After-Treatment.—She was freely stimulated with hypodermics of whiskey and strychnine and subcutaneous injections of hot saline solution. The temperature gradually rose to 103.4° F., and she died eighteen hours after the operation.

Autopsy Ten Hours after Death (by Drs. Selling and Stinson).—The abdomen was opened. The peritoneal cavity contained a couple of drachms of serous fluid. The bladder contained about two ounces of urine. The intestines occupying the lower part of the abdomen showed peritonitis. The gauze in the pelvis was moderately wet and only slightly blood stained. There was no evidence of bleeding.

This is, I believe, the first case wherein vaginal hysterectomy has been performed by enucleation with ligation of vessels only, for puerperal metritis, tubo-uterine abscess, etc. For this reason and because vaginal hysterectomy for puerperal metritis is of sufficiently rare occurrence, I report the case. I am sure that in this case, had the uterus and appendages been removed in the incipiency of the second attack of inflammation, *i.e.*, before the peritoneum was involved, I could have reported a recovery. In operating I avoided serial ligation and the clamp operations. Both of these procedures are open to serious objections, as vital tissues are unnecessarily constricted, with complete interference with drainage from the broad ligaments, which is of great importance in those cases in which the broad ligaments are involved in the inflammation. Hemorrhage from the broad ligaments, etc., can be prevented by simply clamping and tying the individual vessels. By enucleation (with ligation of vessels only), aided when necessary by forceps used temporarily as levers, tractors, and prophylactics, while the vessels are ligated, you do away with mass ligatures, mass clamping, the cautery, sloughing, painful and sloughing stumps, septic discharges, pelvic exudates, wandering and dead ligatures, adhesions, etc.

Soft Soap is preferable to vaseline for anointing the fingers before making vaginal examination and for lubricating the vaginal speculum. It is prepared by dissolving castile-soap shavings in warm water. If the vessel containing the soft soap be surrounded by hot water for a few minutes before it is used, the contents will be of thin consistence, resembling olive oil. The advantages of using this emollient are that it helps to clean the vaginal mucous membrane and readily washes off when it is desired to medicate.—TALLEY.

LICHEN PLANUS PRESENTING LESIONS WITH A CIRCULAR FORM.

BY J. ABBOTT CANTRELL, M.D.,

PROFESSOR OF DISEASES OF THE SKIN IN THE PHILADELPHIA POLYCLINIC AND COLLEGE FOR GRADUATES IN MEDICINE; DERMATOLOGIST TO THE PHILADELPHIA AND FREDERICK DOUGLASS MEMORIAL HOSPITALS, PHILADELPHIA.

ALTHOUGH in the majority of cases of lichen planus which are encountered during the practice of a physician a characteristic formation is shown, there are nevertheless many which present a configuration diametrically opposite. There are many cases of this cutaneous disease which may assume irregularities of distribution, and, while these arrangements may present in variously aggregated patches, others are observed in which they may resemble the appearances of other dermal affections. As usually seen, these cases present lesions which may be discrete in some instances, while in others two, three, or a much greater number of papules may aggregate themselves into groups, accepting no particular formation, but either being rounded or becoming more irregularly placed. Cases have also been recorded in which these papules have been observed presenting a linear arrangement, either when a few have congregated themselves into such a streak or when an innumerable quantity has stretched this line over a considerable area. At times the figurations have formed into circles, while single lesions have shown a tendency to clearing in the centre.

I present the case in this record because of the peculiar tendency of two patches situated upon the forearm to accept a circular form with a clearance in the centre, thus presenting some of the characteristics of an ordinary tinea circinata; and so much so that, were it not for other lesions in the vicinity, it would have created the necessity of recourse to the microscope for a positive diagnosis.

Harry R——, aged twenty-four years, presented himself for treatment through the kindness of Dr. W. O. Xander, of Philadelphia, on March 28th last. His occupation was that of lead glazier, and he had been a sufferer from the present eruption for three months previous to this visit. His health had always been of the best, and never had there been an eruption of any character other than that from which he was now a sufferer. No similar disease had ever been witnessed in any member of his family, as far as he was able to state. Born in Frederick, Md., he had remained in that vicinity until his fourteenth year, when he moved to Philadelphia and began learning his trade, at which he has always been occupied.

The eruption for which he sought advice was observed on the chest and flexor surface of the right forearm. The lesions upon the chest occupied the greater portion of the region, constituting almost a universal condition, but showing areas of healthy skin at infrequent intervals. The lesions were of the small type, but, as usual in the affection, were closely aggregated, although showing no tendency to coalescence. Upon the flexor surface of the right forearm was found the peculiar condition occasioning this paper, owing to the unusual configuration mentioned in the foregoing remarks. The lesions in this locality were rather larger than those observed upon the chest, although they were still of a small size, being of the diameter of a large pinhead in the majority of instances and in others of the size of a half-pea or half-bean. One group of lesions was observed directly over the flexor surface of the wrist and had a diameter of one-fourth inch, being made up of probably eight lesions, all of which showed the rounded or irregular outline with a tendency to clearance in the centre.

The lesion which showed the greatest similarity to the ordinary tinea circinata was observed about two inches above the wrist on the flexor surface of the forearm, it being composed of twenty or more small papules. They were arranged in a ring or circle having a diameter of one and one-half inches, and upon close examination could be discerned to be closely aggregated but having a depression between each, thus showing their individuality. Within the circle there was no inflammation whatsoever, nor was there any tendency to redness surrounding the collection of lesions. Upon the summit of all of these small papules slight scales could be observed, thus drawing one's mind more closely to the superficial ringworm. This ring was rather a continuation of one lesion after the other, and had, as far as this man's knowledge went, been just the same throughout the existence of the manifestation.

Elsewhere than upon the region mentioned there were a number of discrete lesions, and we saw still other spots where two or three had aggregated themselves together. They all showed the characteristic appearances of the affection under consideration, and the diagnosis was made with little difficulty.

The treatment adopted in this case was large doses of arsenic in the form of arsenious acid, the man being given at first a dosage of one-eighteenth of a grain thrice daily, which afterward was increased to one-fourth of a grain thrice daily. Locally he was ordered the liquor carbonis detergens in one-quarter strength. In about five weeks the affection had entirely disappeared, leaving some slight pigmentations over the site of the former lesions.

The uniqueness of this appearance seemed to me worthy of record, simply because of its resemblance to ringworm, and I have described it with the hope that it will prove of some assistance to those who may read this paper.

315 SOUTH EIGHTEENTH STREET.

A CASE OF STRYCHNINE POISONING.

BY ALFRED S. WADE, M.D.

[illegible]

I WAS recently called to attend a man who had deliberately weighed out and taken one grain of strychnine sulphate. He was forty years of age, powerfully built, and weighed two hundred and twenty-five pounds. He was just recovering from the effects of a spree and took the drug with whiskey. After taking the poison he lay down on the bed in his room, and, not feeling any effects from the experiment, took up a book to read, but, he says, was unable to see the print clearly enough to read. He lay there for nearly an hour, when he was called from downstairs by his sister to supper. On attempting to rise he was at once taken with spasms of the legs, arms, and muscles of the trunk. He called out to his sister to send for a doctor at once, that he had taken strychnine. Having some knowledge of medicine, he had his sister give him a teaspoonful of sulphate of zinc dissolved in water. He swallowed this with much difficulty, as he felt a "tightness" of the muscles of the throat; he followed this by a draught of warm water, which failed to produce emesis. When I arrived, a few minutes later, I found my patient suffering intense agony from frequent spasms of the whole body. His body was bathed in perspiration, his face was swollen, and his eyes were protruding.

I immediately injected one-tenth of a grain of apomorphine hydrochlorate hypodermically and gave him by the mouth one drachm each of chloral hydrate and potassium bromide. In a few minutes he began to vomit freely, but at each attempt at emesis was seized with violent convulsions. After the vomiting ceased

I gave him a second dose of chloral and potassium bromide, one drachm each, which I again repeated in one hour. Gradually the spasms left him, but the slightest noise—the opening of a door, and in one case just speaking to him—brought on the attacks in a minor degree. In three hours from the time of my arrival all spasms had disappeared, with the exception of a twitching of the muscles of the face. His only complaint the next day was a "soreness" of the muscles all over his body.

MECHANICAL RESTRAINT OF MASTURBATION IN A YOUNG GIRL.

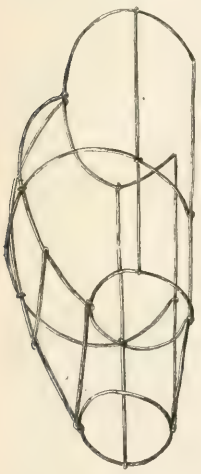
By C. D. W. COLBY, M.D.,

JACKSON, MICH.

A GIRL, aged seven years, slight build, swarthy complexion, black curly hair, light blue eyes, unusually precocious.

She had been taught the habit by vicious children at a "county house," from which she was adopted in the summer of 1895.

I learned from the fostermother that on the advice of physicians she had given her worm remedies, they thinking that, perhaps, the irritation was due to the migration of "pinworms." The parts had been kept thoroughly cleansed; she had been made to sleep in sheepskin pants and jacket made into one garment, with her hands tied to a collar about her neck: her feet were tied to the footboard and by a strap about her waist she was fastened to the headboard, so that she couldn't slide down in bed and use her heels; she had been reasoned with, scolded, and whipped, and in spite of it all she managed to keep up the habit.



On making an examination I found an adherent clitoris, retained smegma, and a redundant prepuce. I broke up the adhesions, cleansed the parts thoroughly, and removed the redundant preputial tissue, thinking this would remove the irritation and stop the habit. She was not made to wear her jacket after the operation (the fosterparents objected to a clitoridectomy), and the first night she tore off the dressings and opened the wound with her fingers, starting up quite a hemorrhage. From that on she was watched till the wound healed and then sent home (fifteen miles) to wait two weeks, while I could devise some scheme to break her of the habit.

The result, which is shown in the sketch appended, is built of No. 8 coppered iron wire, the legs and armpits are protected with sheep's wool, and over the whole thing is fitted a stout canvas jacket. At bedtime the child is slid into the "harness" from the top and the canvas jacket is laced up the back and strapped over the shoulders.

It succeeded in breaking the habit for a year, when she was returned for a new one, having outgrown the old one). She had gained six inches in height and nearly twenty pounds in weight. The habit was resumed as soon as the "harness" was left off at night. I built a new and larger "harness" the first of February and so far it seems to have worked as well as the first.

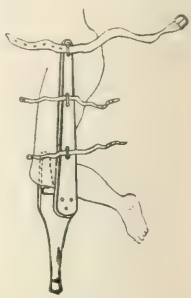
208 SOUTH JACKSON STREET.

A NOTE ON THE USE OF THE PEGLEG AS A PROTECTIVE APPARATUS IN THE TREATMENT OF DISEASE OF THE ANKLE OR TARSUS.[1]

By JOHN C. SCHAPPS, M.D.,

PUEBLO, COL.,

IN examining recently a case of tarsal disease, I was impressed by the patient's ingenuity in securing the protection afforded by a pegleg. The man's name is Michael Sobbi. He was thus able to perform, without injury to his foot, the hard work of a fireman. The apparatus, as shown in the cut, requires no skill in construction or application, and accomplishes efficiently the following purposes: 1. Protection against pressure of weight. 2. Relaxation of calf muscles. Thus the foot can be kept at or nearly at a right angle with the leg without thereby causing interosseous pressure. 3. Diminution of the ill effects of pendency. It permits the application of plaster of Paris or other means of fixation. It renders unnecessary the use of crutches.



The pegleg consists of two slats of wood, attached below to a conical block, upon whose upturned and padded base the patient's weight is received. The block ends in a peg, which should be ferruled. If the patient has to walk upon soft ground, the lower end of the peg should be made broad. The outer strip extends nearly to the crest of the ilium, the inner to a point a few inches above the condyle. The whole may be cut from a single piece of hard wood, from two to two and one-half inches thick. It is secured by straps, as shown.

Kraske's Operation for Carcinoma of the Rectum.—The operation by cutting through the sacrum has not yet obtained that position in the estimation of the profession which its advantages entitle it to possess. The idea of cutting through the sacrum in order to get at the rectum appears to many as such a formidable procedure that they hesitate to recommend it in the early stage of disease when it can be carried out most satisfactorily, and perhaps give it a trial only when the patient himself demands it because his sufferings are becoming more than he can bear. Heidenhain considers that "the only local contraindication to the operation is the extension of the growth to the prostate, bladder, or ureter." There can be no doubt, however, that if the loose connective tissue about the rectum is involved the case is very unfavorable, as it also is if the retroperitoneal glands are affected. Dr. Allison states that "the reported cases of excision of the rectum after Kraske's method for cancer show a mortality of thirty per cent., with a recurrence in forty per cent. of the recoveries. This includes, however, many inoperable cases, as is proved by a mortality of eight per cent. in the hands of some surgeons in properly selected cases." Senn writes that "the surgeon who removes the cancer of the rectum by excision will have a great mortality, while the one who follows the loose connective-tissue spaces, resorts to blunt instruments, and carefully guards against hemorrhage, will show the best results."—*The Lancet*, March 13, 1897.

[1] Read at the annual meeting of the American Orthopædic Association, Washington, D. C., May 6, 1897.

Surgical Suggestions.

Black Eye. — To prevent ecchymosis of the eyelid after injuries, paint the part with the following, avoiding any broken surface:

℞ Mucil. acaciæ ..... ℥ss
Tr. capsici ..... ♏i
Glycerini ..... ad ℥i.
—Da Costa.

Toxin Treatment of Malignant Growths.—In Czerny's clinic (Heidelberg) 27 cases were treated according to the method of Coley. Of these 27 cases 10 were carcinomata, and 17 sarcomata (7 round-cell, 3 spindle-cell, 3 lympho-, 2 angio-, 1 osteo-, and 1 melano-. The following deductions were drawn: 1. In carcinomata the results were completely valueless. 2. In sarcomata, only very exceptional cases showed any result. 3. This questionable advantage was equalized by the dangers of poisoning as well as by the increase of the tumors in other cases.—*XXV. German Surgical Congress.*

The Treatment of Furuncles.—Dr. Louis Dumont (*Annales de Dermatologie et de Syphiligraphie*, tome viii., No. 11, 1896) employs the method of linear scarification used in ulcers and some of the chronic skin diseases, and, according to the author, who has used this method for some years in military service, the results are very satisfactory. The skin over the beginning pustule or boil is first cleaned with a brush and an antiseptic solution (1 to 1,000 bichloride; 1 to 50 carbolic); several parallel incisions are made, a millimetre apart, through the dermis; a similar series is made at right angles to the first; a wet antiseptic dressing is then applied. When this treatment is instituted early in the disease, the pain, redness, and swelling will usually disappear within the first twenty-four hours. The advantages of this procedure are that bleeding is more free, the access of the antiseptic is made more easy, cure is more speedy, and scarring is practically absent.

Urethral Stricture.—1. Strictures of large calibre, that is, of more than fifteen French, situated at or behind the bulbo-membranous urethra, are to be treated by gradual dilatation. 2. Strictures of large calibre, occupying the pendulous urethra, are to be treated by gradual dilatation when very recent or soft, and by internal urethrotomy when of longer standing and distinctly fibrous. 3. Strictures of the meatus and of the neighborhood of the fossa navicularis should be divided upon the floor of the urethra whenever there are real pathological conditions. 4. Strictures of small calibre, less than fifteen French, situated in advance of the bulbo-membranous junction, usually call for internal urethrotomy, preferably with a dilating urethrotome under strictest antiseptic precautions. 5. Strictures of small calibre situated at or deeper than the bulbo-membranous junction should be treated whenever possible by gradual dilatation; in cases of resilient or irritable stricture, which is not dilatable, by external perineal urethrotomy. 6. Impassable stricture of the deep urethra always requires the performance of perineal section.—Dr. Sanders, *New England Medical Gazette.*

Dislocations of the Hip-Joint.—Dr. D. H. Allis (*Dunglison's College and Clinical Record*, March, 1897), in discussing the inward dislocations, summarizes as follows: "The patient lying supine, the surgeon kneels by his side, and if the right femur is dislocated he seizes the ankle with his right hand and places the bent elbow of his left arm beneath the popliteal space: (1) he now turns the bent leg outward by means of the ankle and lifts upward (skyward); (2) then turns the bent leg inward and brings the femur down in extension. Should this method fail, the method by traction should be adopted. The obstacles to reduction are: 1. Lack of skill in the operator or lack of facilities. 2. Obstacles that prevent the head from entering the socket. 3. Obstacles pushed into the socket by the head. 4. The sciatic nerve hooked over the neck of the femur.

Primary or Subjective Causes of Stricture of the Male Urethra.—Dr. Strittmatter (*Dunglison's College and Clinical Record*, March, 1897) felt warranted in offering the following conclusions taken from personal observations: 1. The condition known as urethral spasm, between the bulb and the meatus urinarius, is not due to contraction of the circular muscle fibres, but to either a folding over of the relaxed mucous membrane or the sudden contraction of the cut-off and accelerator urinæ muscle, causing a sudden engorgement of the part subjected to irritation. 2. Post-gonorrhœal stricture is frequently but an augmentation or an infection of a pre-existing condition of stricture. 3. Gonorrhœa, while capable of inducing stricture, very rarely does so without an element of decided traumatism, or without conditions interfering with free urethral drainage. 4. Chronic prostatitis in the aged is always preceded and associated with either an old gonorrhœal urethritis or with conditions interfering with the proper drainage and healthy condition of the urethra. 5. Masturbation, when prolonged, may induce sufficient irritation to inaugurate a stricture, but more frequently the intractable habit is the result rather than the cause of stricture.

Cocaine for Fistula.—The *Medical Bulletin*, November 25, 1896, reported a case of salivary fistula cured by painting with cocaine; the issue of December 2d describes a similar success obtained with it in the case of a fistula of the parotid gland, treated previously with nitrate of silver and chloride of zinc without effect. The solution of cocaine used was five to fifty grams each of water and glycerin. The skin alone was painted twice a week. No result was perceptible at first, but at the end of the second week the improvement was evident and the cure progressed to completion.

Appendicitis.—Dr. J. W. White writes as follows: "Immediate operation is indicated whenever the onset of appendicitis is marked by both suddenness and severity; whenever, during even a mild attack, the symptoms at the end of forty-eight hours are unrelieved or are growing worse; whenever, in cases seen later, a firm, slowly forming, well-defined mass is to be felt in the right iliac fossa; whenever at any time a sudden increase in the acuteness of the pain and a rapid diffusion of tenderness occur; whenever there is good reason to believe the appendix infection to be tuberculous in character; whenever attacks of any type have been numerous, or are increasing in number or gravity, or have unfitted the patient for work or activity, or have caused local symptoms which are permanent or persistent, or have at any time put the patient's life in danger."

Perityphlitis.—Dr. A. Marmaduke Sheild, in the *Clinical Record*, January 20, 1897, writes that that the bacillus coli, associated with other microbes, extensively infects the cellular tissue around the appendix, producing an abscess of varying size filled with peculiarly fœtid pus and gas, which is situated in the right iliac fossa, and usually slowly and painfully works its way toward the skin. It may burst just above Poupart's ligament, or into the intestine, bladder, or rec-

tum, and in females it has been known to point and burst into the vagina. In other cases the abscess, which may be very small in size, transgresses its feeble barriers, and the pus extravasates into the peritoneal cavity. So the affections of the appendix may be divided into two classes—one class in which the part gets thickened and glued down; and a second in which an abscess forms and bursts, or is opened by the surgeon.

The Curette and Morbus Cordis.—Dr. Resnikoff (*Monats. f. Geburtsh. u. Gynäk.*, January, 1897) warns against scraping the endometrium for menorrhagia or metrorrhagia until the patient's heart has been examined. When organic disease of the heart exists, the use of the curette is often followed by an increase instead of a diminution of the hemorrhage.

Carcinoma of the Uterus.—Dr. W. W. Russell concludes a paper upon the "Operative Significance of Metastasis and Post-Operative Recurrences in Carcinoma of the Uterus" with the following propositions: 1. Cancers of the vaginal portion of the cervix tend to advance out on to the vaginal walls, either superficially or beneath the mucous membrane, and if the case is suitable for operative treatment a wide removal of the vagina is indicated. 2. These growths are usually epitheliomata and have little tendency to metastasis. If the local extirpation is complete the prognosis is good. 3. Growths of the cervix are usually adeno-carcinomata, and from their situation are to be considered the most malignant of uterine cancers. The parametrium and bladder are the critical points, and the former should always be removed as completely as possible. 4. Adeno-carcinomata of the body are the most accessible to operative procedure and give the most favorable prognosis.

Society Reports.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, May 17, 1897.

JOSEPH E. JANVRIN, M.D., PRESIDENT, IN THE CHAIR.

The Treatment of Pertussis.—DR. LOUIS FISCHER read the first paper. We must individualize, not generalize the treatment. Each case must be studied separately, somewhat as follows: How many paroxysms had the patient had in an hour or a day? Had he vomited, and how often? Of what did the vomit consist? Were the paroxysms most violent at night or during the day? Had there been any hemorrhages? The temperature? How much food was retained and digested as shown by the fæces? Was the child emaciating or increasing in weight? What was the condition of the heart? What complications existed? In the first or catarrhal stage, expectorants and general hygienic rules, plus concentrated nutrition, cod-liver oil, malt extract, and other restoratives, would relieve and aid in recovery. But if cough persisted, or if we were called in the second or convulsive stage, we must resort to heroic measures. The following headings appeared under treatment: (1) Isolation, (2) clothing, (3) fresh air, (4) the room, (5) medicinal treatment. Isolation was necessary to prevent spreading of the disease. The clothing should be warm, and flannel underwear should be worn both winter and summer. It was Dr. Fischer's belief that more children were lost by injudicious exposure and careless dress than by any other means, for usually those found in a hopeless condition were suffering less from whooping-cough than from some complication or sequel. Fresh air was one of the most valuable means of relieving and modifying the cough. To keep the window open was the cheapest and handiest way to secure oxygen and ozone. If the child's condition permitted, it should be in a park all day. The temperature of the room should be kept at from 68° to 72° F. Sweeping the floor or in other ways raising dust must be prohibited. Let the floor be washed instead of swept. Tobacco smoke, cooking of onions, etc., must be prohibited. Handkerchiefs should be placed in an antiseptic as soon as soiled. Expectoration should be into a cuspidor containing one-per-cent. carbolic solution. In medicinal treatment almost every drug in the pharmacopœia had been mentioned. The tendency in all instances was toward antizymotic agents, local antisepsis, and anodynes. Inhalations of steam, or steam impregnated with carbolic, thymol, or eucalyptol, was recommended by some. The author had tried hot poultices, ice bags, and ice cream, but without benefit. In the MEDICAL RECORD, September 6, 1890, would be found an elaborate paper by him on the treatment of pertussis with bromoform, based on fifty-one cases. Since then he had used it with many successes, and also with poor results in some instances. A pure preparation must be used, given not in solution, but only in drop doses from a spoon. It was very volatile, and should be kept in a well-stoppered bottle, protected from the light. The dose for children was from three to eight drops, three times a day, according to the age. He had one case of poisoning to report from taking too much by mistake, but the child recovered. Chloroform or ether was called for only in urgent cases to relieve the violence of the paroxysm when there was hemorrhage or to prevent rectal prolapse. Belladonna had been an utter failure in his hands. The same was true of atropine. He had discarded antipyrin, and the coal-tar series in general was contraindicated on account of the heart. He had tried morphine and opium with trepidation. Steam inhalations impregnated with ichthyol, a teaspoonful to two ounces of water, had given him good results in children who could inhale properly. This was also true of one-per-cent. formalin inhalations or impregnating the air of the room with it. Menthol seemed best for controlling vomiting, about one grain three times a day. Bichloride of mercury, one-one-hundredth grain, combined with five drops of ichthyol, three times a day, had given good results in some cases in which bromoform had failed. Vaccination with cow lymph seemed to have been of benefit, but only in children not previously vaccinated. Bromides and chloral relieved cough only for the time being. Antistreptococcus serum was injected in one case, without apparent benefit. In some cases of irritable pharynx, rectal feeding was indicated.

DR. S. HENRY DESSAU opened the discussion. He fully agreed with the author that fresh air was one of the most necessary things in the management of pertussis. The sleeping-apartments should be well ventilated in winter as well as in summer. Fresh air and the ozone which it contained was the best antiseptic. He was in the habit of directing the nurse to take the patient to the gasworks of the city, and sit an hour in the room when they opened the purification boxes. The asphalt works could be visited for the same purpose. He also resorted to sulphur fumigation of the rooms, followed by thorough ventilation of them, after which the child was returned. The renewed air was supposed to be then quite pure and germ free. Many mothers had the notion that whooping-cough did not amount to much, yet it was not long ago when it ranked third as the cause of death, directly or indirectly. In looking for some rational treatment, one could not but consider the cause of the disease as some germ, known

or unknown. Therefore benefit should come from remedies having both an antiseptic and a sedative effect, such as antipyrin and phenacetin. He disagreed with the author in his comments upon the coal-tar series, for he had limited himself almost entirely to their use in whooping-cough for some seven years. We ought not to give disagreeable mixtures to children, and for this reason he had discontinued bromoform. Patients for whom it was prescribed at the dispensary were not brought back. For the same reason he had given up bromide and chloral. Enlargement of the bronchial glands at the root of the lung was frequent, especially in children with a phthisical tendency, and when this came on there were likely to be paroxysms of coughing which led mothers to say that there was recurrence of the whooping-cough. In these cases he had found nothing to act as well as iodide of potassium. In patients with chronic intestinal indigestion, alum was useful.

Dr. Quinlan said a child had recently been brought to his clinic with the statement that it had had whooping-cough, that during a paroxysm epistaxis had come on. Its nose was plugged with cotton containing alum, etc. On examination he found the tonsils much enlarged, and on excising them the epistaxis and whooping-cough ceased.

Dr. Fischer thought the benefit from a visit to the gashouse was probably due to the outing. The case related by Dr. Quinlan was one of pseudo-pertussis. Pure bromoform was not disagreeable. It was important to keep up the nutrition of patients with whooping-cough.

Atrophic Rhinitis.—Dr. H. Beaman Douglass read this paper. Atrophic rhinitis presented a loathsome picture, and there was no easy escape from that loathsomeness when once it became established. The scabbing, the horrible stink, the hawking, the difficulty of breathing, the repulsiveness to friends, often made a recluse of the patient, perhaps caused melancholia and suicide. The remedies which had been suggested for its relief included nearly all new and old agents, and pointed to the rebelliousness of the disease if not to ignorance of its etiology. Regarding the latter, search had been made of recent years for some special germ as the cause, possibly with success. The author said that vitiated air, close rooms, dry heat, and crowding undoubtedly contributed to its development. Debility, especially inherited weakness, favored it. It was often seen in persons with abnormally flat, wide nose, and at the dispensary they not infrequently made a diagnosis of atrophic rhinitis at sight when a person with a nose of that form entered the room. In only a few cases was atrophic rhinitis found in an àquiline nose with small nares, and then as a result of degeneracy or anæmia. More frequently complete obstruction would cause atrophic rhinitis of the opposite side. The free side tried to do double work, succeeded for a time, but finally gave up the struggle, and the structures became atrophic. Destructive operative work had in many cases been the cause of atrophic rhinitis. This included work with the cautery and caustics. It had been by this expensive lesson that rhinologists had learned the exceeding importance of sparing gland and vascular tissue. Among the symptoms were headache, both frontal and occipital; cough, nosebleed, dead feeling along the nose, hot and dry feeling, tenderness on touch along hard and soft palates, persistent feeling of nasal obstruction, fœtid odor, scabbing, with feeling of necessity to free the nose. The most frequent place for scabs was about the pharyngeal opening of the Eustachian tubes. Unless it were remembered that all parts of the lining membrane of the nose might be affected, the treatment was likely to be unsuccessful. The treatment related to alleviation of the symptoms, cleanliness, antisepsis, and to the cure of the disease. For practical purposes this division was made: 1, Treatment of early cases; 2, treatment of unilateral cases; 3, treatment of ulcerative cases; 4, treatment of obstruction in superior or middle meatus; 5, treatment of the general condition. Complete removal of the scabs was necessary. The physician should see the patient every other day or every day. When the patient was told to use the douche in the interim, he must be cautioned not to overdouche. The doctor could remove the scabs with a probe wrapped with cotton, wet with some fluid. An antiseptic and deodorizing solution must be used twice a day, to be followed by a medicament if the doctor so directed. Dr. Douglass had douched with light antiseptic, 1 to 100,000 bichloride, and 1 to 10,000 zinc. The electric cautery might be necessary to induce healing of ulcerated surface. Any obstruction must be removed. The general condition required treatment, including exercise in the open air. As to climate, a dry air was best; temperature made less difference. Finally, he knew no specific. Faithful carrying out of treatment must be insisted upon. The earlier it was begun, the better for the patient and the more satisfactory to the physician.

Dr. F. J. Quinlan opened the discussion. In the course of his remarks he said atrophic rhinitis was the terminal stage of fœtid rhinitis or ozæna. The pharynx and larynx participated in the process. As the author had said, the mutilation of soft parts in treatment must be avoided as far as possible in the earlier stage. A fact not mentioned in the paper was that young women, at least according to Dr. Quinlan's experience, were oftenest affected. The odor seemed more marked during menstruation. One author had likened the condition to that of fœtid odor from the axilla, or decomposing smegma. Deafness was a symptom not mentioned in the paper. There was contraction of tissue at the entrance to the Eustachian tubes, perhaps extension of disease to the middle ear. There was a marked kinship between these cases and disease of the accessory cavities of the nose. He thought the nasal douche, as well as acids and caustics, had been a cause in many cases.

Dr. W. F. Chappel remarked that the speakers had confined their remarks chiefly to one form of atrophic rhinitis. In his opinion there were four or five forms, some of them not so serious. There was the rheumatic and gouty form, in which local treatment was not so important, and relief followed remedies directed against the gout or rheumatism. Another form accompanied anæmia, and treatment of this relieved the anæmic, drawn, dry state of the nasal mucous membrane. Then there was traumatic atrophic rhinitis, seen in stonecutters, millers, and persons working in overheated air. A fourth form was that which had been referred to chiefly to-night. In this form he thought more emphasis should be put upon the constitutional influence and the necessity for constitutional treatment against the scrofulous state, etc. He thought ozæna was nearly always of specific origin. It might be a hereditary-syphilis manifestation. Dr. Douglass, he said, had not expressed much faith in oily preparations, but the speaker thought they were of value, after removing scabs, in preventing their reformation. In ordinary atrophic rhinitis he had found nothing equal to iodine. Plenty of cod-liver oil and outdoor exercise should be given.

Dr. T. J. Harris said he would confine his remarks to atrophic fetid rhinitis. According to the common definition, there were three characteristic symptoms which were constant, namely, atrophy of the mucous membrane, discharge, odor. The speaker thought only one of these was constant, namely, discharge. There might be atrophy here, hypertrophy there, and odor might be entirely absent, but discharge

which constantly recurred was never missing. Lowenberg claimed about two years ago to have found the bacillus, but was unable to get a culture which would produce the disease. Later it it had been claimed that the true bacillus resembled the pneumococcus of Fraenkel but with differences, and it had been asserted that ozæna could be produced by introduction into the human nose. Other observers in Italy and France had found the same bacillus. The other theory was the old one of Michel that ozæna always came from a purulent condition of the frontal sinus. Later Grünwald had modified this by saying that there was always a purulent condition of one or other of the accessory sinuses, and, bearing this fact in mind, he claimed to cure his cases. Dr. Harris thought researches into the etiology should be continued, but we ought not to disregard the factor of disease in the accessory sinuses.

Dr. Concanon had treated fourteen cases, in every one of which there was a purulent condition of the ethmoid cells. Five had been cured. Treatment included washing out the ethmoid cells, and use of iodoform-gauze pack, saturated with ichthyol, in the upper part, leaving room below for breathing.

Locomotor Ataxia (?) and Hodgkin's Disease. Dr. Abrams presented a man, thirty-five years old, single; history negative until two years ago symptoms of locomotor ataxia began to manifest themselves, consisting in shooting pains in the lower extremities, absent patellar reflexes, slight swaying with eyes closed and feet together. About a year ago he noticed a mass on the back of the head and neck, and to-day swelling of the glands constituted tumors in the neck beneath the jaw, in the back of the neck; the glands in the axilla were enlarged; the mammæ were also enlarged. It was clear that the man had Hodgkin's disease; had he also tabes dorsalis? A friend had suggested alcoholic neuritis, but the patient drank only occasionally. The interest in the case was the combination of the two diseases.

Amendment of Bylaws.—The following amendment to article v., section 7, of the bylaws was adopted: "Whenever an investigation of charges against a member is undertaken by the executive committee, in regular order, it shall be within its power to cite before it as many of the members concerned as the committee may consider necessary for an equitable adjustment of the matter. Should any member so summoned fail to comply, without valid excuse, he shall be judged in contempt, and it will be the duty of the executive committee to recommend his censure or expulsion from the association."

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, May 24, 1897.

L. C. Gray, M.D., President, in the Chair.

Resection of Pylorus for Cancer.—Dr. Carl Beck presented a man whose pylorus he had resected for cancer. The points made were: Early diagnosis and early operation gave promise of cure; formalin catgut was used, one row of suture, which contributed to the good result, for the patient was able to be up by the ninth day and to be presented on the twelfth day after the operation.

Report of Committee on Legislation.—Dr. Frank Van Fleet read the report of the committee. The committee had been appointed to act with that of the State Medical Society to oppose undesirable bills affecting the medical profession brought before the legislature, and to advocate others. It had very properly and successfully opposed the opticians' bill, which had again been brought before the legislature at its recent session. It had sought to have the charter of the Pedic Society repealed, but had not been disappointed in failure. The amended bill affecting dispensaries had passed the legislature. The committee had started out to do a certain work, and this it had accomplished. On motion of Dr. Van Fleet the members of the legislature who had acted with the committee received a vote of thanks.

Report of the Committee on the Abuse of Medical Charity.—Dr. J. H. Burtenshaw, chairman of the committee, read the report. The first step taken was to ascertain the sentiment of the governing boards of the different dispensaries, and to communicate with the Charity Organization Society with the object of ascertaining what system could be instituted for the investigation of the worthiness of applicants for free medical treatment. A circular was sent to the officials of the ninety-five dispensaries in the city, with three interrogatories, briefly as follows: 1. Did the governing board of the dispensary approve of the movement to abolish or regulate the abuse of medical charity? 2. Would the governing board co-operate with the County Medical Society in this matter? 3. Would it post a placard in a conspicuous place in the dispensary, stating that the ability of applicants for free medical treatment to pay would be investigated? Replies were received from seventy-six. Of the other nineteen, five were homœopathic, two were under the supervision of the department of charities, most or all of the others had a local or limited patronage. The replies were favorable or conditional, with the exception of that from St. Mary's Free Hospital for Children, which treated over seven thousand yearly, and the New York Hospital dispensary, which treated over nine thousand yearly. The committee co-operated with one from the New York County Medical Association and one or more others, and had aided in having the amended Sullivan bill passed in the legislature for the control of charity abuse. The profession throughout the State seemed to be practically unanimous in favor of that bill. The committee had every reason to suppose that the bill would receive the signature of the governor, and had been greatly disappointed that he had not yet signed it, as the thirtieth day since the adjournment of the legislature would expire at midnight. The committee and the entire medical profession fully recognized the fact that there was no charity more beneficent than free medical attendance on the poor, but it had been conclusively demonstrated that the abuse of this had attained such great proportions as to make it imperative to adopt measures to check it at once.

It was moved to accept the report.

The Sullivan Bill too Effective?—Dr. D. B. St. John Roosa said he supposed he was not in accord with the majority of the society, but he thought he would be if they would be kind enough to hear him. He thought the question of the abuse of medical charity had been much exaggerated. He was connected with two large institutions, both of which he had helped to found, and he wished to state that, whatever the medical press might say to the contrary, they were not working primarily for the glorification of the doctors connected with them, but for the benefit of the sick poor. Secondarily they hoped to achieve for themselves an honorable reputation. If there was any treason in that, then they were guilty of it. They took the greatest pains to exclude those unworthy of charity. He thought it would be found that the reason why the governor had not signed the present bill was not that he had not had time to consider it, but that he had considered it. The fatal error in the original bill was that it undertook to give the control of chartered institutions into the hands of a self-constituted society, which had not been born long enough for most members

to know anything about it. The amended bill gave the State board of charities power to annul charters, and to this he was opposed. That power should lie elsewhere when it was proven that the provisions of a charter had been violated.

A point of order having been raised, THE PRESIDENT ruled that Dr. Roosa was not in order, but said he would entertain a motion which would allow the discussion to continue.

The motion to accept the report was carried.

DR. STURGIS then moved to continue the committee, and accepted an amendment by Dr. Grandin to allow $200 to pay for past expenses of the committee. The work of the committee had been great, much greater than would appear from so brief a report.

DR. EGBERT H. GRANDIN spoke for the adoption of the resolution. It was seldom that the society had opportunity to hear so valuable a report as this one on an evil which threatened the medical profession of the city. He was not connected with any institution, and could speak from a somewhat different standpoint from the gentleman who had upheld two institutions with which he was connected, but which nevertheless had helped defraud the medical profession. He was being brought in daily contact with the general practitioners of the city, who told him of their patients who were able to pay an adequate fee going to hospitals and dispensaries where they paid nothing, unless it was ten cents for a prescription or "a dollar a month." He contended that it was just as unethical for a hospital or dispensary to rob him of a patient who was able to pay him a fee, as it was for his next-door neighbor to do so. If there was a body of men in this city who should take hold of this question it was the County Society. We had been speaking and writing editorials on the subject for years; boards of managers had been shown that the charity which they were carrying out was not of the kind the good book spoke of. At last an appeal had been made to the legislature and a bill had been passed, but as it promised something effectual the rich managers of hospitals and dispensaries had killed it. But a drop of water would in the end wear out a stone, and perhaps some day there would be a governor in Albany who would recognize the voice of the medical society of this county. Within a brief period three of his patients, able to pay him a fee, had been taken from him by institutions which charged $15 a week board. Hereafter let the members keep track of all such cases, and let the axe be laid at the root of the evil. The doctors connected with such institutions would learn that it did concern them; that they also must investigate cases coming for free treatment, whatever the managers might do.

DR. F. R. STURGIS said members had been told tonight that there had been a great deal of unnecessary talk with regard to the abuse of medical charity. Pick up the reports of any of the dispensaries and charity institutions in this city, and one could not but be convinced that in each of them abuse of medical charity was practised to an enormous extent. Dr. Sturgis thought the most effectual method of entering complaint under existing conditions was not that suggested by Dr. Grandin, but that each known case of abuse of medical charity should be reported to the State board of medical charities, and that when one knew of a new institution about to be founded he should present facts to that board showing there was no necessity for it.

After several other members had spoken, the president called upon DR. JANVRIN, president of the County Medical Association, and DR. HADDEN, who had just returned from Albany, where they had visited the governor, urging him to sign the Sullivan bill relating to the regulation of dispensaries. They had had an audience of only about ten minutes, but were able in this short time to present their points briefly. They pointed out that at present there was no way of regulating the dispensary abuse; that physicians had no control in the matter; that every dispensary in New York was a law unto itself. More, the different dispensaries would not co-operate with one another in trying to rectify abuses. The whole medical profession felt the injustice of the present want of system, and was practically unanimous in supporting the bill awaiting the governor's signature. It was anxious to leave to the State board of charities the arbitration of the whole matter. If any dispensaries were opposed to this method, it was known that they did not wish the abuses rectified. The State board of charities at present had simply general supervision, but it had no power to regulate the abuses. The governor did not give them any assurance of signing the bill, but expressed the wish that he had heard from them sooner. What that meant, Dr. Hadden remarked, he did not know.

A member asked if it was known who had opposed the signing of the bill, and Dr. Hadden said it was rumored that two men whom he named had done so, one of them a doctor.

Dr. Sturgis' motion was adopted, with few voices in opposition.

Blood in the Urine: How to Verify its Presence and Determine its Source, together with Some General Considerations as to its Causes.—DR. WILLIAM K. OTIS read a paper with this title. The question of blood in the urine interested both specialist and general practitioner. It interested the general practitioner because the patient, greatly alarmed, always came to him first. The presence of blood in the urine might be due to a condition or a lesion of comparative insignificance, or it might indicate one which must inevitably prove fatal.

When the urine contained blood its color first attracted attention. The amount of blood varied from a quantity only sufficient to cause slight smokiness to that which caused a cherry-red appearance. One part of blood in fifteen thousand of urine was enough to cause smokiness, one in five hundred to cause a bright red. The color was due to hæmoglobin, and when this became changed the color might become dark brown. It was a mistake, however, to suppose that when the color of the urine was dark brown the source of the hemorrhage was necessarily in the kidney, not below that point. The use of certain drugs and the presence of bile pigments might impart a color closely resembling hæmaturia. The chemical tests by which to distinguish between this and blood, when microscopical examination was not sufficient, as it usually was, were given. The presence of blood in the urine could also be determined by the spectroscope.

The next question was to determine in what part of the urinary tract the blood originated: Was it from the anterior urethra in front of the compressor urethræ; was it between the latter point and the bladder; was it in the bladder; was it in the ureter or kidney? If anterior to the compressor urethræ, the blood would exude from the meatus, or could be stripped out. The urine first passed alone contained blood. The urethroscope could also be used. If the hemorrhage was from the posterior urethra the blood would not exude from the meatus, but would back into the bladder if of sufficient quantity. If the hemorrhage was small the blood would appear only with the beginning or at the end of micturition, the rest of the urine being clear; or the urine at both beginning and end of micturition might be tainted, the intermediate portion being free. At times a clot might escape. When the hemorrhage was from the bladder the entire urine was mixed with the blood. Microscopic examination might show evidence of a new growth in the bladder. Let the examiner wash out the bladder with solution of borax until the water came away clear, then throw in two

or three ounces, wait a few minutes, and withdraw it; if it contained blood it was probable the hemorrhage was vesical. A further test was the fact that the bladder lining membrane absorbed very slowly except when through disease some portion of it was deprived of its protective epithelium. Let the examiner, having cleansed the bladder, throw in a small amount of iodide of potassium in solution, ten or fifteen grains, wait fifteen minutes, collect the saliva, and test it for iodine by the starch method. If the saliva contained iodine that fact would point conclusively to some lesion of the bladder—assuming that the patient had not been taking iodine internally. He had got this idea from Dr. McBride, but on visiting Germany found it in use there. In case of a new growth in the bladder it could sometimes be felt by rectal examination. The value of an examination by the electrocystoscope could hardly be overestimated. It often revealed the nature of the lesion as well as its seat. In locating hemorrhage in the kidney or ureter, the history was usually of value, for the presence of stone or passage of gravel was apt to give a history of pain. Occasionally, however, hemorrhage from above the bladder came on without the slightest warning. The amount of blood passed varied greatly. Intermittency might be caused by blood clot obstructing the ureter. Dr. Alexander had presented a clot which had been passed, and which was a complete cast of the pelvis of the kidney. The pain might be positive, or only an uneasy feeling. Pain over the region of the kidney might be elicited with the finger when it could not with the whole hand. If the bladder seemed to be the source of hemorrhage which, however, could not be definitely located, suprapubic exploratory incision was justifiable.

Dr. L. Bolton Bangs opened the discussion. There was little to add except by way of confirmation. It had been well stated that the presence of blood in the urine was only a symptom. The important thing was its cause and where situated. The color of the urine was no indication of its source. He had seen urine of bright red color when the source of the hemorrhage was the kidney, not the bladder. The cystoscope might fail to reveal the lesion when this was in the bladder because of discoloration of the injected fluid by active hemorrhage, but this fact itself pointed to the bladder as the source of the hemorrhage in opposition to the kidney. The iodide-of-potassium test had failed several times in his hands when the lesion was in the bladder. He had had a case of profuse hemorrhage whose source was doubtful; he made an exploratory suprapubic cystotomy; the cause was found to be tuberculosis, and the hemorrhage ceased, but recurred when the drainage opening closed. Hygienic measures were employed, and there had been no hemorrhage in two years.

Dr. F. R. Sturgis had found the determination of the source of the hemorrhage in the bladder with the cystoscope difficult even after irrigation when the hemorrhage was considerable. The iodine test had not been of much value in his cases. The author, he said, had limited his paper almost exclusively to hemorrhage in surgical cases. But there were many other causes of hæmaturia, among them certain drugs, supplementary hæmaturia in menstruation, in bleeding hemorrhoids; hæmaturia caused by mental emotions, by parasites, especially in hot countries; by transfusion of blood, in the case of animals, etc.

Dr. Samuel Alexander thought the best test as to the presence of blood was microscopic examination. The other tests, although useful, were rather a refinement. He had found that a good test of whether the bleeding was due to calculus was to have the patient ride on a Fifth Avenue stage and immediately afterward examine the urine for blood. He regarded the Fifth Avenue stage as a part of his clinical armamentarium! As a rule the shape and size and solidity of the clot gave little information, but in his case alluded to in the paper the clot was a distinct fibrinous mould of the pelvis of the kidney and its calyces. Subsequently a renal calculus was removed by operation.

Therapeutic Hints.

Tic Douloureux. — Ewart (*British Medical Journal*) states that in the etiology of this disease the importance of gout in the larvate forms is often overlooked. It may be recognized by the following indications: 1. It occurs often in the healthy with ruddy complexion, which is common in sthenic gout. 2. Presence of Heberden's nodules, or of tophi in the ears. 3. History of gravel or stone. 4. Nervous, gastric, intestinal, and hepatic disturbances of long duration. 5. Strength of pulse and endurance of patient after prolonged pain and insomnia. 6. Adverse influence of alcohol and certain diet. 7. Presence of uric acid in the urine. The nature of the etiological action of gout is not explained, though it is thought to act by producing an irritability of the nervous system. His treatment consists of sedative, restorative, alterative, and tonic measures. As sedatives he recommends morphine and choral; as restorative agents, rest and a non-nitrogenous diet; as alteratives, salts of iodine, mercury, guaiacum, and for tonics the vegetable tonics, massage, and salt baths. The results which he obtained by mercury and the salts of iodine in cases which were not specific are most satisfactory. He gives the histories of several patients about to submit to an operation, who recovered under this line of treatment.

The Treatment of Graves' Disease.—Dr. Hector Mackenzie (*American Journal of the Medical Sciences*, February, 1897) speaks as follows in regard to the treatment of Graves' disease by means of thymus gland: "I am of opinion that the dose, to be of any use, should be at least one or two drachms a day, of the fresh gland or its equivalent in the form of extract or powder. The conclusion at which I have arrived is that the thymus gland possesses no specific action in Graves' disease. I have found it in most cases to have no effect either on the heart, on the goitre, or on the exophthalmos. At the same time it appears to be a remedy of some value, improving the general condition, and, in this way, may assist toward the recovery of the patient. I should, at present, place it in the same class of remedies as cod-liver oil."

The Treatment of Chronic Bronchitis.—Dr. Arthur Davies recently read a paper on this subject before the Hunterian Society. He alluded to the many drugs which had been employed in the treatment of this disease, but he now emphasized the value of the spray method. This was carried out by frequent administrations of ipecacuanha wine three or four times a day. At each sitting one-half or one drachm of the drug was used, but the patients were directed not to swallow the wine. Cases were cited which showed relief from difficulty of breathing and lessening of the expectoration. The disadvantages of the inhalations were that sometimes vomiting followed, and if the drug were used pure spasmodic dyspnœa would sometimes come on, and it was not suited for cases of asthma. Dr. Davies had tried a spray of potassium iodide with encouraging results. The class of cases suitable for treatment with the ipecacuanha spray was early cases with much dyspnœa and tenacious sputa. He had also had much help from the administration of trinitrin, the dyspnœa especially being relieved. When the

dyspnœa was moderate, tar in various forms was found useful. Terebene also fell in the same category. When fœtid bronchitis and bronchiectasis were present, inhalations of creosote have been found efficacious.

For Greenish Dejections.—

℞ Sodii bromid. 4
Syr. rhei aromat.,
Tinct. opii camph. ..... āā ʒ
Aquæ anisi. ..... ad ℥ij
M. S. One tablespoonful every two to four hours.

℞ Lactic acid. 2
Simple syrup 98
Lemon juice ..... q.s.
M. S. One teaspoonful every three hours.

—Hatfield, "*Diseases of Children.*"

Whooping-Cough.—Since Michael suggested nasal insufflations of antiseptic powders, Moizard has also employed them with great benefit. He recommends:

℞ Benzoin (pulv.) 10
Salicylate of bismuth 10
Quinine (sulphate) 2

The insufflations are made five times a day. In a week or less the accesses of coughing are reduced in number and intensity, and the cure is rapid.—*Journ. de Méd. et de Chir. Prat.*

Trismus Neonatorum.—

℞ Ext. gelsemii ..... ♏ viij.–xvi.
Syr. simplicis ..... ʒ i.
Aq. ..... q.s. ad ʒ iv.
M. S. Half-teaspoonful every two to four hours.

—Bartholow.

℞ Tinct. opii ..... gtt. v.
Tinct. asafœtidæ ..... ʒ iss.
Syr. simp. ..... ʒ v.
Aq ..... ad ʒ xv.
M. S. Half-teaspoonful every hour.

—Eberle.

Purulent Conjunctivitis in Infants.—

℞ Hydrastinæ sulph.,
Acid. boric.,
Sodii biborat. ..... āā gr. v.
Tinct. opii deod. ..... ʒ ss.
Aquæ dest. ..... ʒ i.
Mix and filter.

Several bad cases were all cured within two weeks. It should be injected under the lids every hour, and the eyes still more often cleansed with tepid water, and vaseline applied to the edges of the lids every night.—Scott, *Am. Jour. Oph.*

Chapped Hands and Face or Fissured Nipple.—

℞ Tinct. benzoin comp. ..... ♏ x.
Alcohol ..... ʒ ij.
Aquæ rosæ. ..... ʒ ss.
Glycerin. ..... ʒ i.
M. S. Apply to chapped surfaces at night, after washing with soap and water and carefully drying.

—*The Practitioner.*

Mumps.—

℞ Ichthyol,
Plumbi iodidi. ..... āā gr. xv.
Ammon. chl. ..... gr. xxx
Adipis ..... ʒ i.
M. S. To be applied to the swollen parts three times daily. Sometimes vaseline may be used in place of lard and belladonna may be added with advantage.

—Trancmet.

Nervine Tonic.—

℞ Asafœtidæ ..... ʒ i.
Acidi arseniosi ..... gr. ss.
Strychninæ sulph ..... gr. ss.
Ext. sumbul ..... ℈ iss.
Ferri subcarb. ..... ℈ ij.
Quininæ valerian ..... ℈ i
M. Make capsules No. 24. S. One capsule after each meal.

—Brown, *Va. Med. Semi-Monthly.*

Correspondence.

OUR LONDON LETTER.

[From our Special Correspondent.]

SIR R. QUAIN ON THE FIRST SOUND OF THE HEART—PROFESSOR FRASER ON SERPENT POISON, A FURTHER COMMUNICATION—ROYAL COLLEGE OF SURGEONS—NURSING-HOMES—HOSPITAL SUNDAY FUND.

[illegible], July 31, 1897.

The mechanism by which the first sound of the heart is produced is again under discussion. Sir Richard Quain, notwithstanding recent illness and his advanced age, has submitted a paper to the Royal Society on this subject. He attributes the sound to the impact of the blood driven forcibly against the column of the same fluid in the vessels (supported by the valves), which is in a condition of momentary repose. You may be inclined to say you have heard this view before, and certainly it closely resembles if it is not precisely the same as that advocated by the late Dr. Arthur Leared in his thesis, "On the Sounds Caused by the Circulation of the Blood," published in 1861. Dr. Leared even went further, and held a similar view of the production of murmurs. If the stream meets with sufficient resistance in the blood pressure in the aorta and pulmonary artery, what about the valves and ventricular walls? Surely they also offer resistance, and some would say more resistance than the column in the vessels. Be that as it may, the cause of the first sound has always been in dispute, and the venerable baronet, who has always made the heart a special study, may be congratulated on his attempt to settle a knotty question.

Professor Fraser has communicated to the Royal Society of Edinburgh further experiments with serpent poison. He has found that the bile of all animals is antivenomous, but that of venomous serpents is most potent, *e.g.*, ox bile is only about one-seventieth as potent as the bile of the most venomous serpents. Serpents' venom does not seem to be destroyed in the stomach, and yet it fails to poison; so it is also clear that it is not absorbed from the stomach. It is then probable, from Professor Fraser's experiments, that the venom is destroyed by the bile, and we may conjecture that one of the uses of this secretion is to render such organic poisons inert. The antivenomous property of bile does not seem to be soluble in alcohol, but Dr. Fraser has separated a watery extract which displays considerable potency, and thinks that from bile an antidote for snake poison may be produced equal to the most powerful antivenin or antivenomous serum that has yet been obtained from the blood of immunized animals. As bile may perhaps be equally destructive to other toxic agents, it would seem that our views of the functions of the bile should be enlarged and that we may be prepared to learn that it constitutes a most valuable barrier against various toxins formed in the body or entering from without.

Sir William MacCormack has been re-elected to the presidency of the College of Surgeons. The council of the college has followed the example of the Physicians' College in the matter of the medical-aid associations.

The *Morning Post* has admitted a number of correspondents' complaints about the management of nurses' homes. One further charges doctors' secretaries with frauds which if perpetrated would speedily bring them within the clutches of the law. It is rather hard to publish such anonymous charges, without a tittle of evidence, against a whole class of men—charges, too, on the face of them most improbable.

The Hospital Sunday fund still lags behind, and no wonder, for the distribution committee still indorses the clique which is endeavoring to destroy the smaller and special hospitals, though they have given up their separate collectings toward the fund.

Dr. W. H. Robertson, F.R.C.P., of Buxton, died on the 15th inst., aged eighty-six. He had been a prominent figure for more than half a century in Buxton; in fact, he settled there in May, 1836, after he had practised for about five years in Chesterfield. He became physician to the hospital and took a leading part in all the public movements of the town, to the growth of which he so largely contributed that he was sometimes said to have "made Buxton." There is no doubt that his influence did much to extend the reputation of the important mineral waters and to foster the rapid growth of this bracing spa. He was buried on Tuesday, full of honors as full of years, all the town seeming to follow him to the grave. He had been so long associated with Buxton that many thought he must be much older, and I have often heard it said that he must be ninety, but I hear now that he was only eighty-six. He enjoyed the esteem of all his local brethren, as well as of a very wide circle of the profession in London. Of course he had practically retired for some years, but he retained all his faculties to the last, presided at the meeting of the hospital committee, in which he took the keenest interest, as well as those of the Public Gardens Company. He now and again saw patients, and I hear that he did so on the day of his death, which took place rather suddenly that night from heart failure. Buxton is one of our most important inland health resorts. It is situated in the beautiful peak district of Derbyshire, familiar to you from Scott's "Peveril of the Peak," though I believe the "Wizard of the North" never actually visited the locality. The town is nearly one thousand feet above the sea level, and there are higher hills round about, but they cannot be said to protect it from winds. In sunny weather it is hot enough, but on dull days there is always a keen breeze, and out of the short summer season it must be very cold compared with London. I have been there often enough to experience its varying moods. The mineral waters belong to the indifferent class; in fact, "mineral" is a misnomer, for the water contains none and approaches distilled water, unless account be taken of the free nitrogen present. The temperature of this water is 82° F., and the natural baths are considered the most valuable, although there are hot baths for those who cannot take the natural one. The place has from a remote period been celebrated for rheumatism and gout, and in the season is crowded with sufferers from these diseases. Rheumatoid arthritis is often relieved by a course at Buxton, which maintains its repute as our best resort for these chronic invalids, many of whom spend three or four weeks there every summer.

OUR BERLIN LETTER.

(From our Special Correspondent.)

THE NEW TUBERCULIN—PASTOR KNEIPP—CANCER AND TRAUMA—BLACK-WATER FEVER.

BERLIN, July 15, 1897.

THE festivities of the Congress for Internal Medicine, which were reported in detail in my last letter, are all over; members and guests coming from all places in Germany have departed for their individual homes, well satisfied with the work done. Each one pursues in silence his further labors and researches, perhaps to bless mankind soon or in after-years with some valuable discovery. In spite of the distressing heat of the dog days, scientific Berlin works on untiringly.

The first professional opinion upon the new tuberculin was expressed lately before the Dermatological Society of Berlin. As may have been expected, judging by the shortness of time in which this remedy has been before us, there are considerable caution and conservatism indicated in the opinion, which is by no means unfavorable. Of course it covers only the treatment of lupus (skin tuberculosis). Professor Lassar showed five patients who had been receiving the injections for three months, beginning with one-five-hundredth milligram and gradually increasing. He (Lassar) could not speak of a real curative effect, but there certainly was an improvement without any general disturbance of the system. One surprising feature of this treatment is its expensiveness, the daily cost for the five patients being seventeen marks ($4). The other dermatologists present who participated in the discussion all expressed themselves very cautiously; some even took an opposing stand upon the question. Before forming a definite opinion, it would be best therefore to await the results of further careful investigation. If not, there might occur the same wild scenes of seven years ago, when the first tuberculin made its appearance.

As we see the adherents of the medical schools achieving success after success through orrhotherapy, so we note cries of woe and lamentation within the camp of their opponents, the antimedical crowd, at the loss of their leader and master, the world-renowned Pastor Kneipp. The death of this man in Wörishofen, after a lingering illness, on June 17th, is an event which even a medical journal must chronicle. Even though we must regard his working, from a medical standpoint, as harmful, yet we must not class this man with the ordinary run of quacks, for he labored not for personal benefit, but was actuated by love of the human race and a faith in his own teachings. He certainly achieved some good through his warnings to lead a temperate and rational life. While we cannot attack the personal character of the man, yet there remains, on the other hand, the fact that his activity was a most unwholesome one, for the number of the duped patients at Wörishofen is an enormously large one, as every practising physician of Munich can relate. He did much to introduce and widen the use of cold water among the populace, but in no wise did he advance scientific hydrotherapy. Following its originator, the so-called Kneipp system will disappear from the scene.

It is a certain satisfaction to observe in these times, when there is a tendency to ascribe as the cause of most diseases some form of microscopic organism, that some investigators recognize other factors, which are not of a parasitical nature, as playing an important etiological rôle in disease, especially as regards malignant tumors. This is shown by a paper read by Dr. I. Boas, at the Verein für innere Medicin, upon "Traumatic Intestinal Carcinoma, with Especial Reference to Accident Insurance." This question is of vast interest to us Germans, because the law grants a yearly stipend to a workman suffering from carcinoma (or to his heirs in the event of his death), if it can be shown that there was a trauma preceding shortly the appearance of the carcinoma. In sixty-two cases observed by him during the past few years, Boas obtained a history of nine of them. Of these, two were œsophageal cancers, six stomach, and one liver. According to his statistics, Boas finds that heredity plays a minor rôle; three times was there cancer in the ascendants, and seven times among the brothers and sisters. The trauma which entered into the etiology of these cases was received from a few years to a few months previous to the appearance of the first symptoms. The speaker is of the opinion that a carcinoma may remain latent for years until an accidental cir-

cumstance (among others a trauma) may call forth an active cell proliferation. He also believes that a cancer may retrograde, for at autopsies cancers of the stomach have been casually observed in persons who during life never had stomach disturbances. From personal observations and deductions arrived at from general considerations, Boas draws the important practical conclusion that in accident insurance traumatism must be accepted as a cause of cancer. The law does not ask for positive evidence of the relation between trauma and cancer, but merely a strong probability. The verdict of the past few years in accident-insurance cases has sustained this opinion.

At the Berliner medicinische Gesellschaft, Dr. Below reported some interesting facts about the so-called "black-water fever." Long years of personal experience in Mexico and the reports of others in New Guinea have brought him to conclude that this disorder is more closely related to yellow fever than to malaria. He is certain that the melanuria occurs only after the administration of large doses of quinine: that it is, therefore, not a symptom of the disease, but a result of the quinine therapy.

The researches of Dr. Gürber, of Würzburg, cast a new light upon the mooted question of the function of the suprarenal bodies. He first verified the known fact that watery extracts of the suprarenal bodies cause an increase of blood pressure in animals; he furthermore succeeded in obtaining a substance from the extract which exercises a direct contrary physiological effect, viz., diminishes blood pressure. Evaporating the watery extract at 100° C. (212° F.) to dryness, he obtained this new factor each time readily. It is much more poisonous than the substance which raises blood pressure, for after injections of apparently minute quantities into animals, death ensued very soon, with symptoms of cardiac paralysis. Gürber is of the opinion that this blood depressor exists ready formed in the suprarenal bodies, but has remained unknown heretofore because its activity was masked or neutralized by its antagonist, and only after the latter has been destroyed does it become effective. These two substances in the suprarenal bodies really appear to antagonize each other. It has not been possible to isolate them, each for itself. Gürber's discovery is a great advance in the study of the rather obscure functions of the suprarenals. We hope that even this problem will soon be solved.

LINEAR ELECTROLYSIS.

To the Editor of the Medical Record.

Sir: In your issue of July 17, 1897, is a letter from Dr. J. A. Fort, criticising my paper entitled "Results of Chemical Electrolysis *versus* Divulsion or Cutting in Treatment of Urethral Strictures." I nowhere in my paper undertook to determine who was the true inventor of the instrument called by Dr. Fort his "electrolyzer." On the contrary, after exhibiting models of Dr. Fort's and Dr. Butler's instruments, I pointed out the difference between the two instruments, and left the question of priority entirely to the consideration of my auditors. Instead, as Dr. Fort presumes, of assuming that there was but one size of his electrolyzer, I suggested that difficulties regarding the size of the instrument could be overcome by having various-sized instruments.

The next point made by Dr. Fort is that sometimes as high a current as forty milliamperes is used. So high a current would almost certainly pass the instrument through the stricture, but in almost every instance destroy the mucous lining of the urethra; the passage would be obtained rather by cauterization than electrolysis.

Dr. Fort insists that I do not understand his *modus operandi*. Perhaps I do not, but I demonstrated by experiment before the New York County Medical Association that the chemical electrolysis which took place by using ten milliamperes for thirty seconds was so slight as to be hardly perceptible, which statement is verified by the annexed letter of Mr. Livingston:

"July 26, 1896.

"The experiments of electrolysis referred to in Dr. Newman's paper, published in the New York Medical Record of March 27, 1897, were conducted by the undersigned in the presence of the physicians attending the meeting, and the results stated and demonstrated to the society as obtained are absolutely correct in every particular. T. F. Livingston."

I have operated twice according to Dr. Fort's rules, and in both cases caused pain and hemorrhage, with a result very unsatisfactory. A chemical experiment demonstrating a result is a fact, and can be met only by ocular demonstration showing an opposite result. It cannot be "silenced" by observations.

Lastly, Dr. Fort, in his paper, admits that his method does not cure but only alleviates strictures, when he says: "In order to prevent relapses it is necessary to pass a bougie along the canal from time to time." When a stricture is properly treated by electrolysis, the stricture is so completely absorbed that the urethra is restored to its normal condition and thereafter it is wholly unnecessary to pass any instrument through the canal for any purpose. This result I have produced in several thousand cases, some of which are of twenty years' standing, without relapses, and many of which have been investigated by a medical board, and by said board found to be as I stated.

I therefore still contend that Dr. Fort's method of practice is not true electrolysis. My purpose in my former paper was not to criticise any method of treatment, but to compare the various methods of treatment of strictures of the urethra, and to prevent misrepresentation of the method which I have advocated. I claim that such does not cause any pain: the patient is not detained from his business: no tissues are burned or destroyed, but stricture only absorbed by chemical action; no relapses have occurred after a cure has been made: and afterward there has been no occasion for the introduction of a sound or catheter. Such cures have been accomplished in an average of two months, having required a *séance* once a week.

Robert Newman, M.D.

New York, July 30, 1897.

DEFERRED CREDITORS.

To the Editor of the Medical Record.

Sir: I recently took occasion to dun a patient whom I have treated for the past twenty-three years and never received one cent in payment—not even a load of hay or a bushel of oats for my nag. He said: "Doc., I'm liable to pay you most any time. I haven't got down to you yet."

This reminds me of what Samuel Foot said one hundred and fifty years ago, in "The Lame Lover":

"*Sir Luke.*—A pox o' your law. You make me lose sight of my story."

One morning a Welsh coachmaker came with his bill to my lord, whose name was unluckily Lloyd. My lord had the man up.

"You are called, I think, Mr. Lloyd?"

"At your lordship's service, my lord."

"What, Lloyd with an L?"

"It was with an L indeed, my lord."

"Because in your part of the world I have heard that Lloyd and Floyd were synonymous—the very same names."

"Very often indeed, my lord."

"But you always spell yours with an L?"

"Always."

"That, Mr. Lloyd, is a little unlucky; for you must know I am now paying my debts alphabetically, and in four or five years you might have come in with an F, but I'm afraid I can give you no hopes for your L. Ha, ha, ha!"

I'm afraid my man will never get down to P.

H. R. PORTER, M.D.

Diphtheria	[illegible]	[illegible]
Laryngeal diphtheria (croup)	4	2
Chicken-pox	[illegible]	

The Prevention of Tuberculosis.—A writer in a recent number of the *British Medical Journal*, in discussing this question, states that since Koch's discovery it has been manifest that phthisical sputum furnishes the infective material of tuberculosis. Schill and Fischer showed that dry phthisical sputum remained infectious for a long time. Dr. Cornet conducted experiments with the dust of rooms and hospital wards in which phthisical persons were being treated, and found that when no particular care had been exercised in removing infectious discharges this dust contained sufficient infective material to cause the disease when injected into a guinea-pig. Dr. James Niven read a paper before the Epidemiological Society, March 19th, in which he said that the registrar-general's returns showed an enormous reduction in the mortality from tuberculosis during the last fifty years; this might be partially due to better diagnosis and changes of nomenclature, but it was also partly due to sanitary progress. Congenital tuberculosis must be extremely rare. Boltz, in twenty-five hundred and seventy-six necropsies on children under fifteen years of age, failed to find the least trace of tubercle in any under one month; of those between three and six months, 8.6 per cent. were tuberculous, and as the age advanced the percentage of the tuberculous cases increased. Heredity, in the strict meaning of the term, was improbable, though the children of consumptives, like all persons with narrow chests and enfeebled constitutions, were more susceptible to infection. The *British Medical Journal* mentions, as a reason why tuberculosis has not been brought under control, that there is a marked disinclination on the part of many practitioners toward any interference by sanitary authorities with their treatment of tuberculous patients. Dr. Niven advises that spittoons should always be used in the sick-room, and provided in workshops, lodging-houses, railway carriages, etc. He urges the control of dairies, and says that tuberculous milk should not be given unboiled even to pigs. Dr. Willoughby, in discussing Dr. Niven's paper, said he believed that the prevalence of consumption among the native population of health resorts, and the way in which each was in turn discarded in favor of some other, was a result of their becoming saturated with infection. There was no doubt that there should be special regulations in these resorts for the prevention of the dissemination of tuberculosis. Dr. Nocard has called attention to the great faculty of spreading which tuberculosis possesses when it is once introduced into a herd. He shows how easy it is by proper and simple means of isolation to save sound animals. It would be an advantage to have an intercommunication of ideas betwen scientific observers and agriculturists on the preventive measures which may be usefully and economically taken. The pathologist and physician would be stimulated to appreciate and overcome the difficulties which beset the breeder and cow keeper, and the owners would realize the advantages which would accrue from rational precautions. Meat from tuberculous cattle should also be condemned.

An Expensive Testimonial.—A veteran living in the interior of Massachusetts recently gave a testimonial to a patent-medicine manufacturer, stating that he had been entirely cured by the nostrum. It seems that he was receiving a pension for the ills of which the medicine cured him, and that when the authorities learned of his recovery his pension was cut off. Is he likely to suffer relapse? and if he does will he get back his pension?—*Boston Medical and Surgical Journal.*

Effects of Absinthe.—Dr. Pauly, in *La Médecine Moderne*, relates his observations on a man, thirty years of age, who, wishing to commit suicide, took three-fourths of a litre of absinthe. Three hours later he had not vomited nor had he regained consciousness. Injections of ether, artificial respiration, and lavage of the stomach were resorted to. A stomach pump was introduced, and part of the absinthe flowed off almost pure. Forty litres of water, at a temperature of 35° C., were then passed through the stomach. Respiration returned, and the heart became regular, but there were complete coma and abolition of reflexes. The following day the patient died. At the autopsy they found an acute desquamative gastritis, nephritis, with diffuse renal hemorrhages. Alcohol was present in all the organs, but was especially abundant in the brain. Dr. Pauly attributed the symptoms more especially to alcohol, the characteristic effect of absinthe being the production of epileptiform coma. Dr. Lepine did not entirely concur in this opinion. Absinthe is not only an epileptogenic poison, but has also a stupefying principle which would add its action to that of the alcohol.

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service during the week ended July 31, 1897:

PERSISTENT TACHYCARDIA WITH DIGESTIVE AND NERVOUS DISORDERS.[1]

BY W. H. THOMSON, M.D., LL.D.,

NEW YORK.

My attention has been drawn for some years to cases occurring in my private practice of persistent non-febrile tachycardia which could not be accounted for by any inflammatory or structural disease of the heart, nor by any concomitant affection of the kidneys, nor of the brain or spinal cord. Of course also they were not cases of paroxysmal tachycardia, as the rapid action of the heart was continuous for prolonged periods, and when recovered from the subsidence was in each case very gradual. Moreover, in no instance was the tachycardia the only affection present, for without exception this seemed part of a general derangement, of which the most pronounced accompaniments were digestive and nutritive disorders, coupled with serious nervous symptoms, both sensory and motor. While I could cite also similar cases from the wards of my service in the Bellevue and the Roosevelt hospitals, I prefer to quote from my records of private patients, because naturally they were followed up for much longer periods than could be possible with hospital cases.

CASE I.—Mrs. C. H——, widow, aged sixty-five. Seen first, April 11, 1896. Patient stated that she had been quite healthy until some two and one-half years ago, when she began to suffer from constantly recurring attacks of nausea on rising in the morning. At first these would pass off after breakfast, but after some months they recurred often during the day, and for the past year the sense of nausea had been almost constant. During the past year especially she felt that she was losing ground and was growing very weak, all of which she attributed to the state of her stomach. But on November 1, 1895, she developed a series of severe and anomalous symptoms, consisting of violent paroxysmal pains over the head and scalp, with excessive tenderness of the external ears, which became very red, particularly the left. She described the severest pain as radiating from the left ear to the neck, so that she could not lie on the left side. She then had violent neuralgic paroxysms in the jaws, accompanied by stiffness of the tongue, so that she could not protrude it. She also had intense pains in the palms of both hands, and finally in the legs, especially about the hips and knees, but all her pains had more or less tendency to shift. When they occurred, however, whether in the neck or in the upper or lower extremities, the muscles of the affected part became stiff and painful on movement. Latterly she began to have alarming attacks of vertigo, accompanied by a sense of impending death and ending in free vomiting. She could not turn in bed, especially to the left, without inducing dizziness. During the vertigo she had sensations of falling rather than of turning, or else while in bed the whole room seemed to turn round. She had no tinnitus, but I found that she could hear my watch tick only for one inch from the left ear and for twelve inches from the right. At times she had temporary diplopia, but I could find no evidence of paralysis in any of the ocular movements. Occasionally also she had transient but distinct attacks of aphasia, but more commonly of paraphasia.

On examination I found the patient much emaciated, and her family stated that she had been losing flesh markedly since her pains began. The temperature was normal, and remained so or slightly subnormal throughout her illness. The pulse was 156, regular but small, weak and very compressible. No cardiac murmurs. Cardiac percussion area of dulness normal. No tremor in muscles of the face, of the tongue, or of the hands. Knee reflexes normal. No pulmonary affection whatever, no enlargement of the thyroid and no exophthalmos. Liver and spleen normal. As to the alimentary canal, the tongue was small, pointed, glazed, very red, and sore; in a few days aphthæ developed in the mouth and pharynx, as in a patient in the terminal stage of phthisis, making deglutition very painful; the stomach was dilated and tympanitic. There was no epigastric tenderness, no rigidity, and no evidence of tumor or thickening. Bowels habitually constipated. Urine amber colored; specific gravity, 1.025; no albumin or casts, no sugar.

The diagnosis of cerebral tumor had been made by her previous medical attendant, which was apparently justified by her attacks of vertigo, vomiting, aphasia, diplopia, cephalic pains radiating to the neck and extremities, and her continuous wasting. The fact, however, that her first symptoms were gastric and had so continued unchanged for over two years; that her pains were too shifting in character and were so widely distributed over such symmetrical regions as both palms, both hips, and both knees, as well as implicating the jaw and tongue; and that it was difficult to reconcile those about the head with the progressive irritation or pressure of an intracranial growth which would affect both ears, jaws, and tongue, with occasional aphasia and ocular symptoms, and yet without a sign of motor paralysis anywhere, or of any localized anæsthesia, and with normal reflexes—all made me doubt the presence of such a lesion. I once had, however, a patient who had similar attacks of vertigo and of occipital headache supervening upon a chronic purulent otitis, with a long history of progressive wasting ending in death. At the autopsy general chronic pachymeningitis was found, which had been set up by extension from the old ear disease. But in that case there were no tachycardia, no pronounced gastric symptoms, and no pains in any way resembling this patient's. On reviewing the totality of the symptoms of this case, therefore, my conclusion was that the tachycardia, with the nutritive and nervous disorders of the patient, was not due to any inflammatory or organic mischief, and the event proved that this surmise was correct.

A condensed abstract of the subsequent history of the case under my care is as follows: First, the pains of the patient were markedly and rather unexpectedly

[1] Read before the New York Academy of Medicine, June 3, 1897.

relieved by fifteen-grain doses of strontium salicylate three times a day. This at first sight would seem to indicate their rheumatic character, but the peculiarity was that no other salicylate, such as the sodium salicylate, salol, or salicin itself, appeared to approach the strontium salt in efficacy. Antipyrin, phenacetin, and acetanilid had no analgesic effect whatever. I have repeatedly tried the strontium preparation in other cases, but without any such unmistakable relief as with this patient, except in one case to be soon mentioned. The pains were by no means wholly removed, but were so plainly benefited that she continued to take from forty-five to sixty grains a day of the strontium salt uninterruptedly for eight months. On the other hand, an examination of the painful parts showed no correspondence to the signs of a rheumatic inflammation; there was no tenderness on pressure of any joint, no swelling anywhere, and no redness except of the ears. The tenderness on pressure was limited to the tendons and to the fascia of the muscles. There was nothing like peripheral neuritis, or true myositis, for the pains, which curiously stiffened the muscles and made them very painful on movement, in a few hours would shift elsewhere, always excepting the left side of the neck. Unlike rheumatic pains also, they were not affected by changes of the weather, nor were they worse at night. The patient always felt worse in every way on waking in the morn ing. Besides the persistent pain and rigidity of the muscles on the left side of the neck, she had for a long time contraction of the fingers with rigidity of the tendons in the palms of the hands, closely resembling the familiar palmar tenositis of gout. But she showed absolutely no other symptoms of gout, and the pulse was always weak and very compressible.

She was ordered to have a mercurial purge once a week, to avoid all meat and meat extracts, and to live principally on matzoon, kumyss, or peptonized milk, and take fish, poultry, rice, potatoes, and most vegetables, excepting asparagus and celery. Medicinally, besides the strontium salicylate, she took in capsules ten grains each of phenol bismuth and sodium benzoate, three times a day, varied occasionally with the addition of ichthyol. At one time, when the phenol bismuth was increased to forty grains per diem, the urine became dark and showed traces of albumin, so that it had to be decreased to thirty grains daily, which quantity she continued to take without cessation from April, 1896, to March 1, 1897—or a period of nearly eleven months.

The first effect of this treatment was to reduce the pulse from an average of 150–160 down to 110–120. But in other respects she seemed for a long time to grow worse instead of better. The tongue became still more sore, and from April 11th to May 11th my notes show that her nausea was almost constant. She could now lie only on her right side, for if she turned on her back, still more on her left side, the dreaded vertigo would soon come on. During the second month, from May 11th to June 11th, the stomatitis became very troublesome and the aphthæ increased in the mouth and pharynx, rendering deglutition very painful. I may mention that every ordinary prescription for stomatitis was tried without effect, but finally she seemed to be most benefited by infusion of rhus glabrum rhizoma, or sumach. The nausea also persisted as well as the dizziness; the patient continued to emaciate until she had to be padded with cotton batting to prevent bedsores. After nearly sixty days' treatment the attacks of diplopia seemed to become more frequent, her speech was often hesitating or paraphasic, and she was sometimes delirious at night. In fact, her condition appeared so serious that a fatal issue could not have been surprising. I could not see, however, any valid reasons for changing my first opinion of the case, and the treatment was ordered to be kept up without change.

About June 7th the pulse had dropped to 106 and was stronger. The stomatitis was slowly improving. Blistering of the left mastoid seemed to act favorably on the vertigo. The emaciation, however, continued, and the patient had great repugnance to food, owing to her fear of increasing her nausea, which was never absent.

After June 11th the nausea began to be much better. Both the pulse and the nausea, it had been frequently noted, improved for twenty-four hours after she had taken one and one-half grains of calomel in six fractional doses, one every fifteen minutes till the six were taken, which dosage was generally followed by a loose movement in about four hours. She always complained that the calomel made her feel prostrated at the time of action, but the next day the pulse almost always was reduced by ten or more beats and the stomach felt easier, and then in about three days more this improvement would seem to pass off.

On June 22d the excessive heat of that week affected her unfavorably, and the stomatitis returned, as bad as ever.

On June 27th she had an attack of total aphasia, now plainly motor, though before I had regarded it as of the auditory variety. It seemed induced by a bad dream, but I found no signs of muscular paralysis accompanying it on the right side. Before night she fully regained her speech. During this month, however, the dizziness was slowly improving, and one day she told me that she had read some in a magazine, for the first time in a year, as before that reading always brought on a sense of distress in the head.

During the fourth month, from July 11th to August 11th, the great heat of the season again had bad effects, though the stomatitis continued to improve and the nausea became less constant. One most annoying complication then occurred in phlebitis of the right saphena vein, with much œdema of the leg. As the weather improved, however, she began to gain markedly.

About September 1st the nausea disappeared entirely, never to return. She began to relish food, and after a calomel action on September 18th the pulse came down to 92, for the first time below 100. She now began to gain in flesh, color, and strength, and by the end of the sixth month of treatment she was able to walk down stairs.

A month later, in October, she went out driving, and the improvement in November and December was slow but progressive, the chief symptoms complained of being rheumatoid pains in her knees and some discomfort still in the head if she lay on her left side. Through the past winter she has gone about the city with but little inconvenience. Her appearance as to flesh and color is excellent.

The note on March 31, 1897, is that her tongue is perfectly natural; that her stomach gives her no trouble whatever, after more than two years of distress there; pulse, 86, regular and of fair strength, even after quite a long walk to my office; the only symptoms now complained of being occasional pains in the back and legs, for which she insists on taking the strontium salt until they are relieved. She also has some numbness in her toes and some twitching of the fingers.

The last entry is April 28, 1897. The patient can now lie on either side at night, and considers herself quite well. Her hearing is perfect in both ears. Her remark was that whenever she feels mean she takes a dose of calomel, which makes her feel meaner yet for a while, but the next day she is all right.

On thus reviewing the chief clinical details of this case, the question seems pertinent: What disease did

this patient have? That it was a dangerous disease for a time, no experienced physician could doubt. In fact, a really long-persistent tachycardia like hers, verging upon 160, could be no trifling matter, whatever the other conditions were. But in trying to come to a conclusion about the nature of the malady itself, a diagnosis by exclusion may possibly be hazarded. Following the safe clinical rule to begin with the beginning and then keep hold of the first important symptom which maintains throughout a prominent relation to the complaint, we must admit that pronounced gastric derangement preceded for nearly two years every other symptom; also that it afterward accompanied all other developments, until they in turn disappeared with the disappearance of the gastric trouble. That she never had any serious inflammatory cerebral mischief is evident from the fact that she never had any febrile temperature, while it is equally patent that her numerous cerebral symptoms were not due to any tumor or abscess by her getting well of everything when her stomach improved. That she had neither rheumatism nor gout is plain from the consideration that neither of these diseases is preceded by nausea for two years, nor do they give rise to diplopia, repeated vertigo, or aphasia, nor do they occasion extreme emaciation with aphthous stomatitis, or purely functional continuous tachycardia for months together. That she did not have Graves' disease, if by that is meant exophthalmic goitre, was plain by the fact that in her emaciated throat the thyroid seemed atrophied if anything, nor was there the least protrusion of the eyes or weakness of the eyelids, and certainly she had no myxœdema. My surmise at my first visit was that she was suffering from a grave form of toxæmia of gastro-intestinal origin, and the treatment was perseveringly followed according to that supposition. My reasons for maintaining that view were that though an extreme, yet hers was not an isolated example in my experience of what I now consider a definite disease, with characters as special as those of any other affection which has a name, the leading manifestations of which are a persistent rapid action of the heart, conjoined with greatly varied and yet characteristic functional nervous disorders, and apparently accompanied by certain digestive derangements as regularly as diabetes mellitus is accompanied by saccharine polyuria. So definitely associated are these symptoms in these cases that now, whenever I am consulted about certain nervous troubles, I early take note of the pulse, and if tachycardia be present which proves to be persistent and not simply from excitement, and is not to be accounted for by the other well-known causes of cardiac overaction, I then suspect that the nervous derangement is due to this particular malady, and recommend special treatment accordingly.

Case II.—Mr. G——, lawyer, a light-complexioned, fairly well-nourished man, aged forty-two, first consulted me on October 28, 1895. He said that eighteen months before, without any antecedent gastric or other trouble, he was taken quite suddenly one day with nausea and distress in the stomach, which have continued ever since in spite of treatment by a number of physicians and consultants. He has never felt any real relief except for brief intervals while on outings. His symptoms are nausea and an ill-defined sense of distress referred to the stomach, which is not aggravated by eating or worse when the stomach is empty. There is no spontaneous pain there, nor is any induced by pressure. He generally feels worse on waking in the morning and best in the evening. He can lie on his left side as well as on the right.

Inspection showed pupils normal in their reactions, knee jerks normal, no shooting pains, no ataxia. Examination for movable kidney negative. Epigastrium very prominent, and this proved to be due to a decided enlargement of the left lobe of the liver, whose lower border was nearly two inches below the lower limit of the right lobe. There was no enlargement of the spleen, but the stomach was dilated, its tympanitic resonance extending from the sixth interspace to near the umbilical line. Though there was epigastric muscle resistance, yet there were no other signs of gastritis; he stated that he had had his stomach washed out very often, but with nothing excepting clear water being brought up. He says that after every movement of the bowels, even when of natural consistency, he has a sense of having had diarrhœa, which sensation lasts for some time afterward. The urine has been repeatedly examined and always found normal. His tongue was covered with a thick brown fur, and he said that a year ago it was quite black. He did not use tobacco. I found, after a number of countings, that his pulse averaged 130, and was not at all affected by movement. There was no cardiac enlargement or murmur. But besides his dyspeptic symptoms, his chief complaints were of recurrent attacks of nervous prostration, most pronounced on waking in the morning, which made him feel wholly unfit to attend to business. These might pass off in a few hours and he would then go to his office, but they were often accompanied by a sense of weakness and sometimes by severe aching in his legs. These sensations in his legs sometimes came on quite independently of his gastro-intestinal symptoms. He never had any pain or aching in the back, and only occasional headache. When this did occur it was occipital. He showed no signs of muscular tremor, no enlargement of the thyroid; the expression of the eyes was natural.

This patient attended very regularly for a year, and for a number of months his troubles proved very tedious and intractable, being further complicated after a time with obstinate morning diarrhœa. At first I tried a great variety of remedies for dyspepsia, with no better success than my numerous predecessors had. I then learned from him that while living at College Point, Long Island, about fifteen years ago, he had prolonged chills and fever for some three years, which he got rid of only by going abroad. He then had a chill on the third day after getting back, but none since. Accordingly, on the supposition that his present troubles might be due to latent malarial infection, he was treated with full doses of quinine, Warburg capsules, arsenic, and ergot, with counter-irritation over the enlarged lobe of the liver, but without benefit. Meantime his pulse kept up between 104 and 135. His temperature was never noted above normal. Neither digitalis nor strophanthus had any effect upon the pulse, and they had to be given up on account of exciting nausea.

Finally, on February 7, 1896, after a bad week, I determined on a change of treatment, letting his cardiac and gastric symptoms alone so far as medicines directed to them were concerned, and put him on an exclusive diet of peptonized milk with phenol bismuth and sodium benzoate, of each forty grains a day. In a week his diarrhœa was checked and his pulse dropped to 108.

A month later, on March 14th, the record is that he has been much better, has had only one loose movement the past week; pulse, 102; he says that he has counted it down to 90.

After another month, April 20th, he reports that his diarrhœa has entirely ceased, and that his nervous symptoms have so much improved that he has not missed a day from business, although he occasionally has some nausea.

As his pulse still was at 110, I ordered three-grain doses each of ichthyol and salol to be added to the phenol bismuth, t.i.d.

June 2d, he has been improving steadily: has had

none of his old nervous symptoms, no gastric uneasiness, no diarrhœa; liver dulness diminished, but left lobe still larger than normal. Pulse, 98. To continue treatment.

October 19th, just short of one year since beginning treatment, he reported that he kept up the peptonized milk and the medicines until September 20th. Since then he has been on ordinary diet and feels quite well; pulse, 86.

In this case the clinical peculiarity in the history is the sudden beginning of the gastro-intestinal symptoms on a definite day, without any error of diet or other reason to account for them. But to the patient a serious element was the disabling nature of his nervous symptoms, which were both mental and sensory, and which when present made him incapable of mental effort. The effect was as specific and often as temporary as if he had taken a single dose of some paralyzing narcotic poison. It was the regular onset of this condition on his waking in the morning which first excited my suspicions that he had this particular malady, whatever we may call it, for I have always found that these patients feel worse in the morning, whatever their general symptoms be.

Case III.—Miss L. W——, aged forty-two. Patient of unusually equable temperament, without the slightest indication of hysteria. She had commonly enjoyed excellent health. She first consulted me April 20, 1895, for a sudden access of pain in her left ear and left arm, and also an aching under the right scapula. As her eyeballs looked rather yellowish, she was first treated with a calomel laxative for hepatic disorder. These symptoms, however, continued, irregularly recurring, for more than a month, and as they were ascribed to malaria she took quinine from time to time, without further advice, for a number of months.

Nearly a year afterward, April 6, 1896, after having suffered from her symptoms for some time, accompanied by some gastric uneasiness, she again consulted me for pain in the left side of her head. She said that headaches were very unusual with her, but that this pain often centred in her left ear, which became very sensitive to the touch. This symptom, in fact, was precisely similar to the curious ear sensitiveness detailed in the history of Case I. In addition, she had frequent attacks of pain on the middle of the right clavicle, to which she attached a good deal of significance, which I did not understand at the time, but which she afterward explained. She also had pains in her hands and tips of the fingers, especially on the fingernails, as she described them. Pains were complained of also in her shoulders and in the middle of the back. Pulse, 126.

She was ordered fifteen grains of the strontium salicylate, three times a day, and was as much relieved by it as Case I. was. Her other symptoms, however, continued, and more than a month later, May 30th, she complained of an additional ache, rather than pain, in her throat. Pulse, 120.

Patient then went to the country for the summer, so that I did not see her again till September 14, 1896. She stated that she had been feeling badly all summer. Pain was still frequent in left ear. Pulse, 120. But a new symptom was sudden attacks of total blindness in her right eye, lasting some five minutes. The sight then returned all right, but was followed by pain in the eyeball for some time. During these attacks the sight of the left eye was wholly unaffected. She had no diplopia, no hemiopia, no contraction of the field of vision during these attacks (she had been directed to observe for herself, being a very intelligent woman). She had no tremor except in the tongue; this was not fibrillar.

I may here remark that this affection of the eyesight is interesting on account of its resemblance to the ocular derangements of migraine. But this patient had never had migraine before, while this particular symptom occurred in her about the time of life when migrainous headaches begin to decline. I have long held that migraine is of toxic origin, and this disturbance of sight in the present patient would seem to confirm the supposition that her affection is also toxic.

On November 10, 1896, there is a record of pronounced weakness in the knees; also pains about the heart, radiating to the inner surface of the left upper arm; also much pain in the tip of the second left finger. Pulse, 124. No cardiac murmur, no arrhythmia. No enlargement of the thyroid, no exophthalmos, no tremor of the eyelids when closed. The patient stated that she had been feeling much better under the treatment ordered September 14th—exclusive milk diet and intestinal antiseptics, with tincture of strophanthus—until she took dinner at a friend's, where she ate both meat and lobster, the cardiac pain returning on the next day. On resuming treatment, she again improved in her neuralgic symptoms, except that during an attack of influenza, April 12, 1897, she had a severe neuralgic pain referred to the left mastoid and to that ear. The patient is still under treatment, and the pulse continues to range between 110 and 120, but her pains are much relieved as long as she keeps to the milk diet, which, however, is a serious infliction to her.

Now in this patient, as in Case I., we have very similar nervous symptoms, without, however, the serious nutritive disorders which that patient had. It is interesting also to note the control of the pains about the joints, when they occur, by the strontium salicylate; but the other localized neuralgias are not affected by it, nor, as in Case I., are they relieved at all by bromides or antipyrin or phenacetin.

Case IV.—In my experience this variety of pains which the histories of both Case I. and Case III. illustrate is peculiar to this class of patients, and therefore might be very puzzling to account for if the nature of the complaint itself were not recognized. This is shown in the story of Case IV., a Miss G. H——, schoolteacher, who was brought to me recently, May 15, 1897, by Dr. H. W. Kice, of Port Oram, N. J., and which I here include on account of the difficulty in diagnosis which her physician had in accounting for the pains which the patient complained of. I append his history of the case as follows:

"The patient first complained four years ago of a feverish condition, especially at nighttime, when she would be very thirsty. This condition lasted for about two months, being sometimes better and sometimes worse, though she all the time continued about her work. Following this trouble she complained of pain in the heels, particularly in the right—a sensation as if the skin was rubbed off. She says that before any of the above symptoms were observed, for a year or two she suffered from cramps in the feet and calves of both limbs, the right generally being the worse; the cramps sometimes lasted a few minutes, at other times an hour, and occasionally all night. After the pain in the heel had lasted for about three weeks, it went into the entire foot, then both feet; then the feet became numb, as if asleep, the arms experiencing the same feeling. The patient's attention was attracted to the condition of the hands when she tried to pick up a pin or needle from the floor, or anything that required the hands to be down; in fact, simply hanging the hands down caused pain in the tips of the fingers. The hands got very red on hanging down. In walking, the legs from the knees down felt like sticks of wood—stiff. They at first had a sensation as if in ice water, when suddenly they felt

hot, the sensation passing from one extreme to the other. The head symptoms were very noticeable; the first attracting attention was a feeling as if the entire head was in a tight rubber cap. She would also at times experience a sensation of vertigo, or as if the ground were coming up to meet her. Several times on rising in the morning the patient felt pain in the stomach, very severe, running through to the spine. This pain would last for an hour or two, and would subside without treatment. These pains were always more noticeable in the morning.

"I was called at midnight four years ago in October to relieve her of a severe gastralgia, at which time I took the case in charge. The patient lost eighteen pounds in two years, from one hundred and eight she was reduced to ninety. Under treatment she regained the lost flesh, gaining twenty pounds. The general condition has improved, so that the patient now weighs, after four years, one hundred and eight pounds, which was her normal weight. But she has failed to find relief from the other symptoms described above. Her condition at present is about the same. She finds it almost impossible to do any amount of reading without feeling the fulness in the head. There is also a constant desire to close the eyes—not for sleep, but for contentment. A sensation of soreness along the spine, as if having been pounded, is complained of in the morning; also a nauseous feeling, which soon passes off after rising. There is tendon reflex. The pupils react to the light. There is a slight swaying of the body when the eyes are closed or arms extended. There are no lightning pains.

"The above history of the case was taken last autumn. The symptoms have continued since, not constant, but varying; sometimes a few symptoms only annoy the patient, at others there would be much suffering. In April last I saw her for a severe gastralgia. The pain was severe in the right side. Pain has been most constant in the left side for the last two months. The bowels are constipated. The patient is troubled with insomnia; she passes perhaps one night a week without sleep. Heart action rapid, 120 per minute."

Examination: Patient pale and emaciated, with an anxious expression. She said that besides her other pains she had lately had a severe pain in her right ear. The character of the pains showed that they were not due to peripheral neuritis. Knee jerks and other reflexes were normal. Pulse, 130. Her physician said that he had never counted it below 120 for four years. There was no enlargement of the thyroid, but patient said she often had a sense of tightness there. There was no exophthalmos, but the palpebral fissure was widened and the lids were very tremulous on closing, especially the left.

In other cases the gastro-intestinal symptoms are the chief manifestations for which the patients seek advice, as in Case II., and here again, so long as the nature of the malady is not recognized, the treatment is naturally directed toward remedying the supposed digestive derangements, but with most disappointing results as regards both stomach and bowel troubles. I have been struck with the total failure of all the reputed remedies for derangements of the stomach, including lavage, which in these patients have proved useless, when faithfully tried either by myself or by others before me. This disappointment is still more likely in the treatment of the diarrhœa, when that is present. In these patients it is a painless watery flux, coming on in the morning, but the frequent sense of uneasiness in the bowels is always accompanied by bad feelings in the head and a sensation of general depression. Astringents only increase this discomfort, and they control the looseness but temporarily. Of course the continued absence of a febrile temperature with the tachycardia must be carefully noted, in order to exclude the presumption of tuberculosis. Another mistake in such cases is to rest content with the adoption of that equivocal term, "neurasthenia." All the symptoms of nervous weakness may be present in these cases, and I have found that every antineurasthenic remedy has been tried, from strychnine to hydropathy, or I have tried them myself, without any permanent benefit, as the record of the following shows:

Case V.—Mr. J. C——, cashier, aged forty, consulted me first, June 13, 1894. This gentleman has a sister, whom I treated for epilepsy of seven years' duration in 1881, and from which she quite recovered, so that I was not consulted again by her for fifteen years, when she came with symptoms of Graves' disease, from which in the course of about a year and a half she also recovered. Mr. C—— consulted me, as above, for persistent gastric and intestinal uneasiness, accompanied by almost constant occipital headaches and spinal achings; he slept badly, awoke unrefreshed, and always felt worse in the mornings. What he also especially complained of was tremor of the right hand, interfering with his signing checks. Pulse, 104. As he seemed a very nervous subject and a chronic dyspeptic, he was treated accordingly throughout 1894, but with very varying results. In 1895 my notes show him still complaining of frequent sense of prostration, constant feeling of pressure in the head and pains in the eyes, pulse not falling below 100, and with frequent attacks of palpitation and continued tremor of the hand. He had often taken quinine on the hypothesis of malaria, but if anything felt the worse for it. Headaches were most relieved by ten-grain doses of antipyrin and twenty-grain doses of ammonium bromide, repeated in two hours and always taken in the morning. Throughout July, 1895, he had morning diarrhœa, with much increased tremor in the right arm. The rest of the story of 1895 is that of ups and downs, the patient feeling best when giving up all business and going on a long vacation in the country, the morning diarrhœa then ceasing of its own accord. He relapsed, however, on returning to the city, and January 1, 1896, he complained of aching in the right shoulder and neck and upper part of the right leg, with a feeling of general nervousness. He had been taking cod-liver oil and various tonics. For a time he seemed to improve under arsenic and ichthyol, with sodium benzoate at night, but my notes in April and May and June, 1896, record frequent returns of his morning diarrhœa, which was always painless; also early waking with feelings of gastric distress, severe neuralgic pains in the back of the head and neck, for all which he again tried the country cure. He was not benefited, however, and returned August 10th, with severe morning headaches, prostration, very troublesome palpitation, tinnitus, tremor of hand, and pains in the eyes. I should mention that I sent him on this account to Dr. Carl Koller, who reported that nothing in the condition of his eyes accounted either for the pain in them or for the headaches. He was accordingly put upon the treatment for persistent tachycardia with digestive disturbance and nervous symptoms—namely, abstinence from meat, matzoon diet exclusively, with sparing use of vegetables, on account of his diarrhœa, and a blue pill once a week, with phenol bismuth and sodium benzoate.

The notes that I may cite are, first month, September 11th, diarrhœa stopped; still has headaches, but lessening in severity.

October 7th, feels generally better; treatment continued.

March 7, 1897, has not reported all winter because he felt so much better; has been continuing treatment faithfully. Pulse, 80.

As this patient recovered from his tachycardia, the tremor of his right hand improved so that he could use it again. But the tendency to headaches and morning depression returned again, April 27th, and still continues at the last date, May 31st, though the pulse is only 76. He avers, however, that nothing makes him feel so well as the blue pill, as the next day after taking it is the best in the week. Such relapses must be expected in chronic digestive troubles of whatever kind, but the improvement during the past winter is so evident that the patient is well content to persevere.

I have had several patients with this form of persistent tachycardia, who complained much of pain in the eyes, generally, however, along with headaches similar to those experienced in this case.

Thus Miss B—— first consulted me, February 8, 1894, for daily severe headaches with pain in the eyes, always worse in the morning on waking, suggesting, therefore, that use of the eyes did not cause or at least did not aggravate the headaches. Dr. Koller also examined her eyes, and reported that there was nothing in them to account either for the pain or for the headaches. Her pulse, counted at repeated visits, ran from 130 to 140. Under treatment, outlined as above, her symptoms all improved in about two months.

Case VI. — Miss C. B——, aged thirty, music teacher, first consulted me for this condition, October 21, 1896. This patient's trouble could easily be mistaken for a case of hysteria, as she was very nervous and emotional and had so many troubles to complain of—as insomnia, constant headaches, pains in the eyes, pulsation felt in the head and, as she averred, in the neck also, with pains at the last cervical vertebra and coccygodynia. She, moreover, especially dreaded her fits of mental depression. She was also much disfigured with pustular acne. Her appetite was poor, and she complained of great gastric discomfort, without, however, symptoms of gastritis. At repeated visits from October, 1896, to May, 1897, the pulse ran generally above 120, but at the last visit it was 94. I mention this case more for the purpose of directing attention to the symptoms of mental depression, which, I think, in this class of patients is very frequently misinterpreted as hysterical. I have for many years, when the question of this protean disorder of hysteria has arisen, been accustomed to rely on certain, to me, distinctive mental accompaniments, the undoubted presence or absence of which has determined my diagnosis accordingly. Of course this element, in this cerebral complaint, cannot be described in a word; but to say that hysteria must somehow be spectacular perhaps comes nearest to my meaning, as it implies that mental disposition illustrated in the anecdote of the Frenchman, who was complimented on the emotion which he displayed at the funeral of a friend. "Ah, but you should have seen me at the grave!" was his reply. There is something dramatic about the hysterical patient, even when she is dumb, which is distinctive. Now in this patient, and in others with this form of tachycardia, there is often much nervousness present, but it is not in the least spectacular, any more than the approaching delirium of fever is; and observation of the action of the heart soon proves that its rapid action cannot be due to emotion. The presence of true tachycardia must be based upon repeated careful examinations of the pulse, for nothing is more common than mere emotional quickening in weak or nervous patients. When due to excitement it will invariably be found to vary on the second or third counting at the same sitting, upon the patients becoming accustomed to the proceeding, and very likely not to be present at all at the next visit.

In this patient the last note, May 7, 1897, was: "Feeling much better; pulse, 94; headaches greatly improved. Finds great help from ten-drop doses of strophanthus tincture, especially against nocturnal palpitation."

I may mention that I have found the action of this drug very variable with these patients, some finding it beneficial, and others not, especially if it disagreed with the stomach.

It will readily be inferred from the prolonged history of most of the foregoing cases that their treatment may tax to the utmost the patience of both patient and physician. I do not wonder, therefore, that some cases which I have seen in consultation with other physicians have illustrated the pathology of the affection more than its therapeutics.

Thus Mr. J. N. S——, sent to me by Dr. Charles S. Kerley, of this city, November 12, 1894, a fairly healthy-looking young man, aged twenty-four, came with a story of constant diarrhœa for six months, coming on when he rises in the morning and very watery in character, and which lasts till 10 A.M. His chief complaint, however, is of sudden attacks of great prostration, which may occur anywhere in the street, when he feels as if he were going to drop and lose consciousness. This state may last two or three hours. I found his pulse 110. Dr. Kerley stated that he had suffered from these attacks of prostration for three years, following, according to the patient, an attack of the grippe, since which he had never felt well, and that from the beginning he had rapid heart action, though the diarrhœa was, as stated, of but six months' duration. This patient afterward returned to England, and the change seemed to do him the most good.

Another patient, Mr. A. J. C——, aged thirty, literary man and artist, was referred to me by Dr. W. R. Chichester, of this city, February 3, 1897. His mother had lifelong migraine, as he described it, in one eye. He suffers from peculiar headaches, which are preceded or accompanied by a sense of great distress in the bowels, described variously as pain, nausea, and great general nervousness. They often set in as suddenly as a fit. No ocular symptoms. No albumin or sugar in the urine. The pulse is very rapid and irregular, but as I saw him only once I cannot state how persistent the tachycardia is. Dr. Chichester, under date of May 26, 1897, writes: "For a time Mr. C—— seemed to improve under the administration of the antiseptics you prescribed, with the weekly dose of blue pill. Later on he began to lose flesh and strength, and was drifting into a state of mental depression. These phenomena would appear to come on when he could not get his matzoon and partook of red meats (beef). About a month ago his condition was most deplorable, and at that time I stopped his medicine and fell back on the old pil. asafœtida, as his nervous condition at times became one of frenzy. The increased heart beat and the intestinal pain seemed to be coincident. His diet during the last month comprised everything except red meats, although he has confined himself to matzoon in the main."

As to the pathology of this affection, it appears to me that some insight into the problem is gained by a study of the peculiar pains and their accompaniments which have been described in the histories detailed. As a class they appear characteristically to differ from the other varieties of pain which we usually meet. In the first place, they certainly are not inflammatory, for they present no signs of local exudation or infiltration or swelling, and they are more shifting in character than true inflammatory pains. Though apparently developing often in the fascia of muscles and their tendons, yet they are rarely affected, as all inflammations of fibrous tissues are, by alterations in the weight of the atmosphere, such as presage the advent of a storm. Also, though sometimes resembling peripheral neuritis, yet they produce no changes in the normal re-

flexes, as, for example, in the lower extremities, no matter how long they have been complained of there. They are not accompanied either by any more muscular wasting than comports with the general emaciation present. The same may be said of the accompanying numbness or paræsthesia, as in Dr. Kice's case, in which the patellar reflexes were just normal, neither increased nor diminished. Just as certainly they are not degenerative pains, for I have never found localized anæsthesiæ, whether of pain, touch, or temperature. They differ also from pure neuralgias in being accompanied by distinct local arterial hyperæmia, and by producing a peculiar stiffness of the muscles, with pain on movement. But this stiffness, totally unlike the tetanic reflex contraction of the periarticular muscles of an inflamed joint, was also unlike the inflammatory stiffness of muscular rheumatism, for example, because it changes rapidly, sometimes by simply altering the position of the limb, as if the arterioles of the part had lost their tone and the blood in them was affected by gravity, giving rise, moreover, to that subjective sensation of inward pulsation all over the body, which these patients often complain of when standing. Moreover the tremor, so frequent in these patients, never had the characters of a clonus or of any analogous reflex phenomenon. A closer examination into these symptoms seems to connect them, instead, with a state of general arteriole dilatation; the condition of the ear in Case I. being precisely similar to that of the ear of a rabbit in whom the sympathetic in the neck on that side has been severed. It might be surmised, therefore, that paralytic arterial distention, particularly in the vasa nervorum, is the proximate cause of many of the pains, especially those felt in the abundant plexus of the tips of the fingers and in the toes. On the same hypothesis I would account for the pains in the eyes and ears and the accompanying interference with their special functions.

I may add that a patient of this kind under my treatment once lost the sense of smell for several months, following upon a headache which was relieved by an attack of epistaxis. The relief which blistering of the mastoid afforded to the pain and deafness in the left ear in Case I., with improvement of the vertigo, does not invalidate the inference that the aural trouble was not inflammatory, for the blister may have relieved the arterial hyperæmia of the part simply by the well-known effect of the vasomotor stimulation which is produced by counter-irritation.

Lastly, it may well be asked: What morbid process of an organic kind, whether inflammatory or degenerative, can involve such symmetrical areas as hands and feet, knees and hips, both ears and both eyes, besides the motor branches of the fifth and the hypoglossal nerve, and likewise cause aphasia—all of which phenomena were present in Case I.? In fact, we may say that not a sign is wanting in these patients of a state of the vascular system which is summed up in the term vasomotor paralysis, and that the distribution of the symptoms is such that it cannot correspond to any systemic affection of vasomotor tracts or centres, but must be brought about by an agency operative through the circulation itself—all of which is equivalent to saying that that agency must be toxic in its nature. On this theory we might infer that the tachycardia also is not a local affection, but due largely to the general loss of arterial tone, though this does not exclude a direct effect as well of the toxæmia upon the heart itself.

The next question is: In what direction are we to look for the origin of the toxæmia? The clinical evidence, it appears to me, points strongly to the alimentary canal as the primary seat of the mischief, owing, in the first place, to the fact that in the history of these patients distinct digestive disturbances precede, often for months or even years, both the tachycardia and the nervous derangements. If the gastro-intestinal symptoms dated only from the time that the other derangements were first noted, still more if they developed subsequently to the tachycardia, this presumption would not be so strong. Instead of that, I have not failed, on careful inquiry into the previous history of every one of my patients, to find that they had been long subject to digestive disorders, very often of quite a characteristic kind. Thus both the gastric and the intestinal derangements in these patients rarely have presented the signs of catarrhal inflammation. The stomach troubles, instead, are more like those which migrainous patients complain of, while the intestinal disorders comprise habitual constipation or simple watery diarrhœa, accompanied by a sense of uneasiness in the bowels and of depression rather than of pain.

In the second place, when improvement in the action of the heart and in the nervous symptoms takes place, the improvement invariably has been preceded by improvement or cessation of the digestive disorders. About this clinical fact there can be no mistake, and hence it is difficult to resist the conclusion that the relation of the gastro-intestinal derangements to the others must be causative, when we find that the latter neither begin nor end without the former have first begun or ended.

We must await the progress of chemistry to demonstrate what the supposed poison or poisons are which, generated in the alimentary canal in this affection, are then by absorption productive of the specific symptoms. Here again clinical experience seems to indicate that it is in the digestion of certain highly nitrogenous articles of food that the occasion of the trouble arises. Repeatedly I have found all the symptoms of the patients as distinctly aggravated by indulgence in red meats as indulgence in starchy food aggravates the symptoms of diabetics. In one patient even the flesh of fowls caused derangement, though, with most, poultry in moderation is allowable. A milk diet, however, when made digestible by artificial fermentation or by peptonizing it, is by all odds the most conducive to restoration, and in many cases so distinctively curative in its effects that it affords of itself a strong presumption of the digestive origin of the complaint.

As to diagnosis, the presence of the specific tachycardia is the leading element. It would be difficult to cite an affection whose symptoms might be more obscure or baffling than this one, whether in the rebellious dyspepsia or bowel disorder, or in the curious and protean character of the nervous symptoms, until the clew is furnished by the concomitant rapid action of the heart. Failing to note the presence or to appreciate the significance of this functional cardiac derangement, we may vainly try for months to treat the alimentary canal or the nerves with our measures with as little success as if we gave tonics to a diabetic for his weakness or stimulants for his nervousness. On the other hand, digestive disorders, however well treated, always require patience and perseverance, and in this complaint this principle is particularly applicable. If the patient will agree to follow a systematic course only for a month or so, no cure should be promised.

Finally, we may ask: Is there any disease which is at all comparable in its symptoms and nature to the affection which we have been illustrating by these clinical examples? The answer is that undoubtedly Graves' disease does so in every respect, except in the addition of two symptoms, neither of which was present in the cases which I have detailed, but which two symptoms, on account of their obtrusiveness when present, have given it its most common name, exophthalmic goitre—most unfortunately, as I think. In Graves' disease we have digestive disturbance, cul-

minating in severe cases in marked emaciation without fever, and in a large number with a tendency to persistent diarrhœa. In a large proportion these digestive disorders are specifically associated with a variety of sensory and motor symptoms in different parts of the body, such as neuralgic pains, disturbance of the special senses, local paralyses, muscular tremor, vasomotor derangements, etc. Lastly, there is the same rapid action of the heart. But because the thyroid enlarges and the eyes protrude, that disease has been regarded as a purely thyroid affection, when it might as well be called an eye affection, for sometimes goitre occurs without exophthalmos and exophthalmos without goitre. In many cases also the patients suffer severely with the general symptoms of the complaint for months or even years, before any enlargement of the thyroid or exophthalmos appears, and then when these do appear they vary in degree from time to time up to complete disappearance and then recurrence. The mischief of naming diseases after inconstant symptoms is twofold, in that the disease may not be recognized when actually present because these particular symptoms are not developed, or it may lead to erroneous views of pathology by inconstant symptoms being interpreted as causative, which they never can be if they are inconstant. A real cause can never be absent from its effect.

In this list which I have detailed this evening, not one of these patients had either goitre or exophthalmos. Two of them have this feature connected with them —the gentleman, Case V., who has a sister who once had exophthalmic goitre; and the lady, Case III., who also has a sister five years older than herself, whose history I published in my second communication on Graves' disease in the *New York Medical Journal*, October 10, 1896. In this patient, Case II. of that paper, the first complaint was pain on the anterior aspect of both thighs at night, then distracting throbbing in the left ear, then tremor of the right arm preventing writing in the morning but not in the evening, with other characteristic and, some of them, very distressing symptoms, along with a pulse of 130, but no goitre from 1893 to 1896, when it suddenly developed, curiously enough, just as all her other symptoms were markedly improving. Meanwhile up to this week, as I saw her on June 1st, instead of the goitre increasing her troubles, these have wellnigh disappeared, and the thyroid enlargement comes and goes irregularly without much discomfort so that the patient cares nothing about it. Therefore if she had not, after three years of her trouble, finally shown enlargement of the thyroid, I should now have included her story along with that of her sister's. The fact is that one sister has exophthalmic goitre and the other has not, but both have Graves' disease. On one subject, however, both sisters, who are exceptionally intelligent ladies, express deep regret—namely, they are convinced from their own experience that their mother died of the same disease. She was sixty-four years of age when she died from exhaustion after an illness of four years, during which she was attended by several of the most eminent physicians of this city, none of whom ventured to give a positive diagnosis of her complaint. According to their statement she had first for three years a great deal of gastric trouble with frequent vomiting. She suffered from much palpitation and had sudden attacks apparently of heart failure. One physician said that she would die from heart disease, but that it was not valvular. She had a great deal of vertigo; then severe pains in the toes and then in the fingers; then recurrent phlebitis occurring twice in both legs, but from which she recovered. She had attacks also of transient blindness, and finally a severe pain in the right clavicle with some swelling there, which a distinguished surgeon said was in her condition an inoperable tumor, but which would grow till she succumbed to it. From the description I judge that it may have been supposed to be a subclavian aneurism, but the surgeon had to change his mind afterward, as both the tumor and the pain in the clavicle disappeared. I give this account for what it is worth; but the lady who furnishes it is fearful that the pain which she has had herself in the right clavicle and the attacks of blindness in the right eye, above described in the history of her case, ominously remind her of her mother's experience. I may mention that the statement of the phlebitis naturally interested me, on account of its supervention in Case I. of this paper.

If, however, the pathology of the cases now reported by me is that of toxæmia of gastro-intestinal origin, the same I hold to be true of Graves' disease itself. The enlargement of the thyroid then may be regarded as due to overstimulation of the thyroid cells by the presence of a toxic irritant in the blood. It is not an improbable theory, in fact, that one of the functions of this gland is to neutralize by its secretion poisonous materials constantly absorbed from the alimentary tract, and that it is only their excessive quantity in Graves' disease which causes it to become relatively insufficient to its task. We can only refer here to the experimental researches of Breisacher, Ewald, Rosenblatt, and Benissovitch, who agree in reporting the rapidly poisonous effect of a meat diet on thyroidectomized dogs, while the number and intensity of the symptoms are diminished on a milk diet, indicating that a normal function of this gland is to prevent injury from products of the normal digestion of what is a natural food with these animals. On the other hand, the many curious effects of the blood condition, in producing both motor and paralytic affections in nervous tracts, may also be the cause of the exophthalmos. Exophthalmos, and sometimes enlargement of the thyroid, have been reported by Filehne as the result of the division of the restiform bodies in rabbits, which phenomena therefore would seem to be induced by a paralytic impression on medullary centres, a deduction which is further borne out by the paretic symptoms in Graves' disease of the Stellwag and von Graefe signs.

THE PHYSICIAN, HIS PERSONNEL, AND HOW IT AFFECTS HIS SUCCESS.[1]

BY F. J. HILLIS, M.D.,

NEW YORK.

The Physician.—Of all the pursuits and occupations engaging the attention of civilized man, there is none so trying and so grinding on the nervous system as the practice of medicine. Men engaged in other walks of life, and the people at large, have as a rule regular hours in which to transact business, appointed hours for meals, a time for rest and amusement. The day laborer, the lawyer, the artist has regular hours for repose. These periods are dedicated to sleep, a heritage to be maintained, an institution to be perpetuated. No ringing at their doorbells at unseasonable hours, no jumping out of bed half-awake at a moment's notice, no running out into the darkness half-dressed, no solitary walk through miles of street under angry and unpropitious skies; for the doctor no holiday, no Sunday, but weary years of toil; no church bell to summon him to devotion, no process server to remind him he is a citizen. Occasionally, in the monotony of tumult, he receives a sudden jar when the bailiff comes to eject him for non-payment of rent; however,

[1] Read at the thirteenth annual meeting of the Fifth District Branch of the New York State Medical Association, May 25, 1897.

happily this is of infrequent occurrence. He is exempt from some obligations, only to be a slave to others. His vocation is to be ever waiting and always ready—a bondman *de facto*, while a citizen *de jure*. He would be discomfited and destroyed by these accumulated woes, were he not buoyed up by the consciousness of doing good. Here the poison and the antidote are companions of a journey.

Dwelling in the midst of alarms and a witness of so many tragic scenes, no matter how steeled his heart, the effect is felt and the image reflected; there the negative or shadow finds an abiding-place, and the development will come slowly or may suddenly be precipitated by a favorable condition. Excitements will begin to tell at fifty-five on the floor of the heart, roughening its naturally smooth surface and binding down its longitudinal fibres, rendering the doors or valves leading to the main arteries leaky and inefficient. The circular fibres of the arteries supplying this floor, the vasa vasorum, contract too, narrowing the lumen of the vessels and destroying their function, when atheromatous or calcareous degeneration ensues. Now the condition known as endocarditis exists, and few physicians at sixty-five are free from this pathological sequence.

After sixty there is a sort of chronic inflammation, progressive and increasing, according to the labor or excitement to which the physician is exposed. There is no temperature range of any consequence attached to this contraction and thickening; in fact, the temperature may often be subnormal. This might on general principles be designated as dry rot. Old trees are subject to this disease, too. The old tree rots at the heart, as the saying goes, while the young tree dies at the root. The old man's nervous system is not so impressionable as that of the young. It has not the elasticity to rebound or the potential energy to summon quick reinforcements. The old man's heart is a storm gauge. It receives the blows and they are registered on the endocardium. He may be unconscious of the manner of reckoning, and indeed even of the blows, but excitements after sixty will have a cumulative and finally a disastrous effect, and the saying will go around: "He died of a broken heart; that news he heard yesterday killed him."

Not Interested about Himself.—It is a well-known fact that the physician is careless about himself, sometimes to a degree of fatuity. While interested in his patient's heart murmur and the pallor of his patient's cheek, he thinks not at all of his own. He will examine with great minuteness a blood disc from his patient's artery, to determine its ratio to the standard of health, and investigate the source and quality of a murmur with care; while his own heart is weak, its valves are faulty, with murmurs long and loud, heard everywhere over the areas of exploration. He trusts himself to the mercy of the elements, chance, and perennial hope, while he builds a wall of protection around his patient and formulates a treatment that will withstand a vigorous bombardment from disease.

When He Will be Reminded that there is a Limit to His Endurance.—At sixty-five the surgeon should hand his scalpel to a worthy brother, younger than he. Many reputations have been ruined by not knowing when to quit. He should not imitate the pugilist and wait for a knock-out blow before retiring. After that age he will have a tremor in his hand, and the eye will grow dim in spite of glasses; even though the mind is as clear as running water, and its reasoning perfect, it cannot control that tremor of the hand. Then let him retire gracefully when he feels that the touch of time is upon him, for none should know better than he that nature is inexorable and will not be trifled with. If he further persists from habit or vanity in the vivisection of his fellow-beings, he is very likely to be the subject of some good-natured ridicule in the operating-room by the younger men around, and even by the neat and keen-visaged nurse at his elbow. Each day brings poorer results. There is nothing to be hoped for but retrogression in his methods. There is no time here. He is looking backward. He wants to grasp again the triumphs that younger and brighter days had brought him, to prop him up in this, the hour of his sore distress. Through the dim vista of the past he discerns the phantom flying and sees the lurid flame —forbear, good doctor—

"To tempt the dangerous gloom."

He takes the step heedless of the warning, and disappears from the scene.

The physician at seventy should take in his sign and seek a quiet retreat in the corner of a consultation-room. He is now admirably adapted for giving advice. The stored-up experiences of years have an inestimable value here. If he further persists in active labor and launches again on the stormy deep, his hulk will founder, since it is leaky, shrunken, warped, eaten by the resistless fury of the elements and weighed down by the incrustations of time, a prey to the conditions that are the offspring of age and complements of senility and decay.

His Discipline.—The well-disciplined physician will not worry too much if things do not go to his liking in the sick-room, or take it to heart if he loses a patient suddenly and unexpectedly. If he does, the sooner for his peace of mind and health he enters another pursuit the better for him. The constant fretting will wear his mind and consume his body, and while yet young he shall be gathered to his fathers and join the majority beyond.

The wise physician will forget the pains and tribulations of the sick-room after the door is closed behind him. In that room let him think and use his skill and judgment well, give his instructions in an easy yet emphatic manner, not recapitulate except on special occasions. Often for this cause good doctors have been accounted bores, and patients have disappeared from their lists without their knowing why.

The physician must not be too sympathetic in the sick-room, or carried away by the tears and sad faces he sees around him. He must be like the sturdy oak in the forest—bend to the blast, while not being affected by it. He must always keep himself well in hand, never lose his temper or presence of mind; if he is master of himself, he will seldom have difficulty in being master of the sick-room. He must be ever conscious of the fact that the family did not send for him for the purpose of sympathizing with them; their friends and spiritual adviser are abundantly able to do this, and more too, for it will be found that the former, and unfortunately often the latter, indulge in criticisms not overfavorable to the physician. His method of treatment will be measured by his degree of success, and, if failure perches on his banner, a cute and knowing friend in the background comes to the front to whisper into the ear of the distressed relative: "I told you so; I said all along he did not understand the case."

The nature and character of the disease play no part with these people. It is always a question of the degree of ability of the physician.

His Trials.—It cannot be too forcibly emphasized or too often repeated that humiliation has come to the physician because of his kindness of heart and ever-ready sympathy. He is doing excellent professional work to save his patient, and has hope he can pull him over the crisis. He neglects other patients whose money is sure, for this one whose money is not sure, but whose promises are inflated and extravagant: he has taken a special interest in this case, is in the sick-

room early and late, watches all the symptoms, and combats every unfavorable turn.

At the crisis, and while he is preparing to see this patient, who is the first on his morning list, his door-bell rings violently, a small boy hands in a note directed "To the Doctor."

On the previous evening a patient promised to send the doctor a fee that was long overdue. His heart was full of glee and words of thankfulness were on his lips as he was about to break the seal. He felt he was rather hasty on the previous evening, when he sent a tart note requesting the money, and when the word was returned that it would come in the morning he felt that human nature was not quite so bad as he thought—and he is now about to be in possession of that fee! The doctor tears the envelope with confidence and hope. He opens the letter. There is no money in it! He is disappointed. He is further disappointed, surprised, and disgusted when he reads:

"Dr. Kindheart: A friend of ours, a lady, Mrs. Lightbody, from across town, called this morning to see your patient. She is not satisfied with your treatment and thinks that Marguerite is growing weaker; consequently she summoned her own physician, who is now in the house. Please do not call again until we send for you.

"Very respectfully,
"Mrs. Lighthead."

A physician was called out of bed in the night to see a child suffering from croupous laryngitis. The physician was not young, nor was his health vigorous. The night was bitterly cold, and the sick-room to which he was called was anything but comfortable and congenial. He went home for his case of instruments, returned to the sick-room, performed a delicate operation, and remained through the night, lest an emergency should arise demanding his immediate presence there. His treatment gave instant relief and promise of final success. Tired and worn out by the labors of the night, the physician turned his thoughts on home. After giving directions as to the course to be pursued in his absence and until his return in the morning, he left the house, enveloped in an atmosphere of prayers and praise by the good people of the family that his days might be long in the land and prosperity always lend him her smile; they would never forget his skill and kindness as long as they lived, and would without fail pay him for his night's services when he returned in the morning—just then they were so overcome by their feelings of gratitude and emotion that money was of small consideration and of minor importance. He came according to promise in the morning; as he entered the apartments he met a member of the family, and in reply to the query, "How is your brother?" he was told: "Doing well now, but two hours after you left this morning he had a change for the worse, and we thought it wise to summon another physician, who has left positive orders that no person be allowed to see the patient but my mother, who is in attendance until his return. We would have sent you word not to call, but were too exhausted after the fatigue of the night to pay any attention to a thing of such small importance."

Recognizing the Situation.—An experience or two of this sort every week will bring the physician to his senses, and after a while he will get it through his cranium that people do not send for him to prescribe for them because they like him, or because they entertain a regard for him above or beyond other members of his profession. They call him in because they believe he can do the best possible for the sick one.

Ingratitude.—When they are convinced or imagine some one else can do better, they throw him down like a dishrag. They have, as it can be seen, no regard for his feelings or gratitude for what he has accomplished. They will trample him in the dust in their haste to bring some one else, not so competent as he, to carry on the work he so auspiciously began. The homely saying, "Don't swap horses crossing a stream," has no weight here, for these people do a great deal of swapping—the further down in the social scale the more so—and during this swapping there is swamping, for the new horse often throws his rider, not being so surefooted as the old one. This will account for the awful mortality in crowded tenement districts in times of sickness or epidemic. They play with doctors as a child plays with toys, and change their doctors oftener than they do their underclothes, with the result that "too many cooks spoil the broth." It is hardly necessary to say the cooks don't get paid. It is the common lot of all physicians to have such experiences some time or other during their professional career, and those with quick perceptions and fine nervous organizations suffer the most from the base and cowardly ingratitude and often atrocious conduct of these miscreants, calling themselves human beings and claiming a common humanity with us.

"Who knows thee well, must quit thee with disgust,
Degraded mass of animated dust."

It takes about ten years' observation to know and understand the dear public, for whom and among whom we labor, and about twenty years to have a fair knowledge of human nature, as it presents itself inside and outside the sick-room.

His Charity.—There is no profession so charitable or so ready to give its services away. The physician, if properly approached, will never say "No" anywhere and everywhere that his services are needed. In an emergency he is there, binding up the wounds of the injured or ministering to the wants of the sick; in that hour of peril he is as brave as a lion, prodigal of his labor and skill, and as kind as a sister of charity. This professional gentleman is ever alive to the appeal of the needy, and always ready to relieve a fellow-being's pain. If he is apparently deaf to entreaty and slow to respond to a so-called emergency call, he has just cause for his action, and will in every case be able to show that the seeker after his services is worthless and undeserving of consideration, and, after all, not really in need of his services at all. He has broken faith with this physician many times before, and is prepared to do it again when the occasion presents itself. If the people kept faith with the physician as the physician does with them, there would be little need of that institution known as the dispensary, and that other colossal concern, the hospital, would shrink to its normal proportions. Then would the board of governors cease to play the rôle of mandarins, the superintendent that of Turkish pacha: then would the physicians and surgeons attached to those establishments be emancipated from serfdom, and the hospital itself cease to be an engine of oppression.

His Habits.—There is a saying among the people that "all good doctors drink;" that if a patient is fortunate enough to catch the doctor sober, his case will be speedily diagnosed and recovery rapid.

It is not an unusual proceeding for several sick people to be on the lookout for the doctor, as at this period the mind is in a formative state, and, like the elements, in a nascent condition, eager to form new combinations and liberate latent force. At this transition stage his touch has a healing influence, and the words that fall from his lips are charged with potency and promise.

Physicians not overburdened with practice, having in mind this popular delusion, often rapidly spring into favor by simulating intoxication. Before he was commonplace and little noticed. Now attention has

been directed to him; he has exploited himself at opportune moments; the people in the marketplace and on the thoroughfare recognize that the mental processes and nervous energies of this physician are rapid, interchanging, and extremely exhausting, and that after all he is only paying the debt he owes to genius. He must have a stimulant to restore his nervous equilibrium, and what is so rapid in effect and so easily assimilated as alcohol? He cries for it and appropriates it with celerity and gusto. In time the mist will have cleared away and the popular illusion will have vanished, but often not before the physician retires with a competency.

His Triumphs.—The triumph of the physician is complete when after his patient is dead the family speak of him with respect and esteem. Death drew them closer together, and now binds them, as it were, with hooks of steel. Their loved one was too good to linger long here below. He was called away to fill a measure of usefulness beyond the vision of our grossness, but only to realize the fruition of our hope. Happy is the physician who can multiply these experiences, for his yoke is made easy and his burden light.

The Status of the Giants of the Profession. — It will be observed that the giants of the profession, the college professors and great practitioners of the day, are not, as a rule, the medical advisers of the four hundred. Their profession with them is the serious business of life. There are too much intensity and force of character in them to allow them to be obsequious and over-obliging. In their effort after knowledge they forget to cultivate the art of pleasing and the subtle ways that hypnotize and control—no polite aphorisms in the drawing-room, that leave behind fragrant memories and make the ladies' breasts thrill with emotion as they anticipate new and repeated *séances!* These men have no tricks, no sly ways, no cards up their sleeves, no surprises to spring, no pleasantries to relate. Their appearance will bear evidence of this; features rugged as the granite hills, strong to resist the force that is in them, the *vis a tergo* of the mind—faces always impressive, often implacable, terrible when confronting stupid opposition or condemning imposture and hypocrisy. These homely faces reflect thought and pent-up force. Men with faces like these make history, revolutionize society, and rearrange the maps of states and countries.

The rubicund and unctuous belongings of the prestidigitator and Don Cæsar de Bazan of the fashionable sick-room are all absent here. Plain and direct, life has an object and time a value to him. He is businesslike and brief in the sick-room. He came there for a purpose; that purpose accomplished he retires without ostentation; in fact, these great men carry the odor of the counting-room and the directness of the bailiff into the sick-room so conspicuously that their presence is seldom welcome there. For this reason they are seen in the portals of swelldom only when the angel of death is hovering over the house and Gil Blas is fearful that he will not be able to bear the burden of disaster alone.

His Personnel.—The personal qualities of the physician are always to be reckoned with on the balance-sheet of success or failure: his magnetism, his ability to attract or repel—in short, all the details, items, and attributes that make up his personnel. This will not consist of a strained and awkward effort to please, or of any effort on his part. It will be a quality or condition peculiar to himself, and of which he may be wholly unconscious; however, it contains the elements of success, the force to impel him along.

The versatile and dashing physician has neither the time nor the disposition to pour over cumbersome tomes and consult authorities on medical topics. He has an assistant to do that for him; to tell the truth, he has no great liking for these same authorities, for are they not too prosy, too dreary, and altogether unsatisfactory as to conditions and final conclusions? Who can blame him for wanting none of them? It will be seen later he is a law unto himself, and a higher law. To his mind they are well-meaning but honest fools, toiling and bearing the burden in the heat of the day, while he is regaling himself at the opera or admiring the scenes from art or nature from his dogcart in the park or driveway.

> "While the author is wrestling with the problem of disease,
> His forte, to wheedle, manipulate, and please.

He has the genius or inspiration to distinguish between conditions, and determine beforehand and anticipate the quality of fatality. In the drawing-room his smile is expansive and illuminated; his features are mobile, impressionable, and pleasing. After casting an auspicious horoscope for the young lady at the piano, and assuring her mother that youth yet lingers with herself, that it is not difficult to discern whence her daughter's ready wit and beauty came, he talks of the opera, what constitutes a dancing set, which is the best French play, criticises the latest novel, and anticipates the fashions for the season; he also says a word about golf, and incidentally mentions Newport and Lake George. These varied topics form an uninterrupted chain; the subjects blend into each other like the coloring in a landscape, and please the eye while amusing the fancy.

In the sick-chamber upstairs he drops his light and airy fairy ways. His face is a picture now (a veritable Jekyll-Hyde transformation)—features contracted, cold, and thoughtful; language measured and slow; manner severe and aggressive. He is diagnosing the case. His ponderous mind is like a sea swept by the fury of the gale. The intensity and concentration of thought are terrible. His mental perceptions have grasped and solved the problem; the diagnosis is complete. He apprehends disaster, though there is no danger signal flying, no high temperature, no rapid or irregular pulse, no respiratory sigh flashing like sheet lightning with ominous torpedo-like explosion; and, with gravity mingled with emotion, he informs the friends of the patient that pneumonia is about to develop, but he thinks it can be aborted or diverted, or, as the electricians say of the current, "grounded;" so he furnishes the conductor, a lightning-rod, in the shape of a placebo, gives some details to his nurse, says he will send his assistant to the house immediately and that he will call himself in the evening, jumps into his brougham, and is driven to the matinee. On his return from the matince he visits a flower show at the grounds of the Horticultural Society. At home he instructs his assistant in some minor details and dispatches him again to the sick-room. This assistant is often a clever fellow, and understands his business well. He is ever mindful that his first and only duty is to please his master. To this end he is diplomatic and crafty; nothing to affect his reputation, nothing to detract from, nothing to compromise his employer ever falls from his lips. He is as silent as a sphinx, thoughtful as a philosopher, and companionable as an owl.

How It Affects His Success. — The master is drowned on a yachting-cruise, and the mantle of success falls on this scholarly hack. He puts it on, but it is a hideous misfit. He would like to wear it, but it makes him look so ridiculous. It is so altogether out of proportion that he is not certain where to begin in order to remedy the inequalities and restore its symmetry. At a conclave of his friends it is decided that a change in construction would ruin the mantle. There is now nothing left for the hack but to wear it

himself or give it away—but it will fit none of his friends; a spirit of loyalty to his departed leader, however, prevents him from pursuing the latter course, and he dons it himself. He suddenly recovers his voice and grows quite loquacious. He is called professionally to a house, not unknown to him, but one that his lamented predecessor knew so well. In the drawing-room he talks of the physical aspects of the moon, the solar spectrum, and the belts of Jupiter, drops a few words in commendation of Milton's "Paradise Lost" and Gibbon's "Decline and Fall of the Roman Empire," and concludes with a reference to Munkacsy's "Christ before Pilate." Upstairs in the sick-room he is simplicity itself, and readily takes the family into his confidence. He declares that at present there is no danger, that it will be four or five days before symptoms are sufficiently developed to permit a positive diagnosis. In treatment he speaks about digestive ferments and assimilants; he also speaks like one having authority on leucocytosis and bacteriology. He departs with quiet dignity. His last words are: "If a change should come for the worse, be patient and hopeful, and immediately notify me." He hails a street car, and alights at the rooms of the Historical Society.

The drawing-room below has a frosty atmosphere from his presence there. His dissertations and admonitions upstairs fell on unsympathetic ears. He is now standing alone, no shadow of greatness to hide him from the fierce criticism that beats with relentless fury on his head. The shafts of slander that are hurled at him from feminine tongues strike in vital parts. His enemies are numerous and still increasing. His patients are one by one, like autumn leaves, falling from his daybook; they drift with the tide of success, while he is left high and dry on the shore of disappointment and despair, to ruminate on the fact that ability and skill in his profession are only a small part of the armamentarium of a successful physician, and that, though he may masquerade in his master's clothes for a while, he will in time be discovered, and in the end his defeat and humiliation will be more complete.

Some physicians fail who are thoroughly equipped. They possess all the elements of success, but, unable to control or to utilize the force that is in them, they are overwhelmed and destroyed.

> "Viewed his own portion on the field,
> And winged the shaft that quivered in his heart."

Others fail because they had ideas and expectations of easily and suddenly acquired wealth. The medical schools are to a great extent responsible for this sort of failure. They hold out great expectations to the aspiring medico, and often fill their catalogues with glittering generalities, which speedily evaporate into thin air. The student is charged and primed in the lecture and class rooms with this elusive philosophy, and longs to pluck the golden fruit that he sees dangling in the orchard of popular favor. But alas! a rapidly flowing torrent separates him from the realization of this dream. He cannot hear the roaring waters as they are precipitated over the cataract, or see the gulch below; but the rapid pace he is running will bring him face to face with it soon, and his impetus will fling him into the whirling eddy, where too often these troubled waters hide him and his blasted hopes. He perished because his alma mater did not sufficiently instruct him, and impress the fact on his mind that the road leading to success is hard and rocky, circuitous and full of inequalities, abounding in pitfalls and cañons; and further, that eternal vigilance is not only the price of liberty, but of success as well. In his haste to acquire wealth and fame he failed to acquaint himself with the difficulties to be encountered in pursuit of these objects.

Success in the practice of physic, then, depends not on the knowledge one possesses on that subject, but on the nice adjustment of the various mechanisms that enter into a perfect whole. The mental faculties must be rounded out by a keen appreciation of human nature, and of the fact that while this human nature is an element to be considered in any social equation, it is especially conspicuous and prominent in the practice of medicine.

[illegible]

SOME IMPORTANT POINTS FOR CONSIDERATION IN THE TREATMENT OF ACUTE LOBAR PNEUMONIA.[1]

BY LOUIS FAUGÈRES BISHOP, A.M., M.D.,

[illegible]

[illegible] SECTION [illegible] MEDICINE, NEW YORK ACADEMY OF MEDICINE; MEMBER OF THE [illegible] OF ALUMNI OF ST. LUKE'S HOSPITAL [illegible], ETC.

THE proceedings of our medical societies are sometimes criticised by superficial observers, and by those who do not take an earnest part in the work, for the frequent recurrence of old topics and the absence of novelty and originality. Such persons mistake the office of the scientific medical society and the motives of those workers who can always be counted upon to express freely, honestly, and with humility what they know or to acknowledge their ignorance of any subject that may be brought forward. The object of the work is more to crystallize truth than to disseminate what is new. Such novel information has a spreading power in itself that easily carries it to the whole profession. In the medical society men gather to compare, correct, and fill out their experience. Here the immature views of young men germinate and develop, while even the oldest has his established beliefs pruned into better form by free discussion.

The introduction of the subject of pneumonia without the excuse of any original observations, without any new statistics, or any favorite plan of management, requires only the excuse that we are still seeking the best plan of treatment. Every physician has some mode of procedure that he has acquired from his preceptor or has carried from his hospital. That any one shall approach the treatment of a case of acute lobar pneumonia with confidence of a successful outcome is impossible, so long as the present death rate remains. A mortality approaching twenty-five per cent., which has not been materially diminished in modern times, is certainly sufficient excuse for free and frequent discussion.

There are two ways in which the treatment of disease may be improved: By a gradual improvement in the details of treatment, with a better appreciation of the disease and an improved technique; or some specific treatment may be discovered suddenly to supplant all previous plans and immediately reduce mortality. The improvement in the treatment of typhoid fever is an illustration of the first; diphtheria is an instance of the second. A number of specific treatments of pneumonia are claimed each year, but improvement is still confined to the elaboration of a better technique.

I will touch upon four points—feeding, the prevention of delirium, hydrotherapy, and stimulation.

As to diet. In acute lobar pneumonia it has always seemed to me that the tendency was rather to overfeed. It is questionable whether, in the acute stages of the disease, with the undoubted accompanying congestion of the abdominal organs, harm is not often done by stuffing the stomach with milk to the production of large quantities of gas and upward pressure on

[1] Read before the New Jersey State Medical Society at Atlantic City, June 22, 1897.

the diaphragm. Now and again a feeble voice is raised against overfeeding in pneumonia. The lesson of feeding in other febrile diseases has been so well learned that the shortness of the course of pneumonia is not enough considered. There are undoubted benefits in restricted diet in a disease so acute. Overfeeding means a consumption of physiological force in the digestion and assimilation of food. It means the diversion of so much energy from the reparatory forces of the body to the digestive forces. It means throwing into the circulation a quantity of crude food products that must be taken care of. It means the presence in the intestinal canal of the waste matter of the food that must be gotten rid of. The patient dying in acute pneumonia does not die from a lack of reserve force, such as might be produced by a system of stuffed feeding, but rather from the failure of the development when needed of the latent force already existing. If by a system of overfeeding, such as would produce this more remote force, part of our stock of immediately available energy is used up, more injury than good is done. It is just as if the captain of a ship with an important and pressing commission should stop to replenish the coal supply on the wharf when he should be on his journey, burning the supply in his well-filled bunkers. Diet should be bland and moderate in quantity. It would seem that only a misconception of the conditions of pneumonia leads to stuffing.

There is no disease in which it is more important to discount future events. An acute delirium in an alcoholic patient, when fully developed, frequently means a fatal termination. The feeble power of drugs to control this delirium, short of paralyzing the patient with dangerous doses, is only too well known. If at the outset of pneumonia in an alcoholic case we foresee that the day of delirium is bound to come, we can by the free use of safe sedatives avoid or at least limit the delirium of the later days.

The bromides are not sufficiently appreciated for their good qualities in acute disease. Their harmlessness has been so impressed upon me by the experience of treating a large number of epileptics, who took continually enormous quantities, that it has seemed desirable to consider their usefulness in other conditions. The reason that the bromides have so little reputation in emergencies compared with morphine, chloral, hyoscine, and the hypnotics, is that they have been given in too small amounts. Other drugs get more fair treatment. We push them until we accomplish the result aimed at, or until the appearance of some danger symptom. With bromide, single doses of from five to thirty grains are too often given, and then resort is had to some other expedient. A solution of bromide well diluted is not irritating to the stomach. It resembles very closely in its chemical and physical properties the saline salt solutions that we do not hesitate to put directly into the veins. It is not poisonous in any dose that any one would possibly apply. Its most glaring defects are the size of the dose and the slowness of the results. The fear of bromism that is constantly before the mind rests upon a foundation chiefly of tradition. It occurs in patients who have been taking large quantities for a long time, and is the result not simply of the drug itself, but of mixed causes, such as gastric irritation and deficient elimination.

If the alcoholic pneumonia patient is brought from the beginning of the disease under the influence of bromide in efficient quantities, the use of the more powerful and dangerous sedatives at a later period may be avoided. After delirium is once thoroughly established in pneumonia, bromide is a drug too mild to be efficacious. It should be begun in the very beginning of the disease in alcoholics and given freely, so that the patient shall get from one-half ounce to one ounce in the twenty-four hours. Lives seem to have been saved in alcoholic cases by the free use of bromides from the beginning.

The third point in the treatment of pneumonia that can well be discussed is the value of hydrotherapy. In going over the recent literature of pneumonia as found in the later text-books and systems of medicine, a restlessness and reaching out for new methods is perceived that is not found in the older ones. While we do not find among the conservative men who are usually selected as the authors of these books one who definitely recommends the exclusive use of hydrotherapy, still nearly all point to it as a possible or even probable improvement, and quote some other man in support.

The great problem that confronts us in this disease is the maintenance of the circulation in spite of the obstruction of the consolidated lung. To get the best results of management, we must regard the circulation as a whole, not concentrating our attention entirely upon the heart or the pulmonary circulation or the systemic circulation, but always remembering that what benefits one part of the circuit cannot but affect favorably the other. The stimulation of the heart and the use of vasodilators to relieve its burden are important, but hydrotherapy is not frequently enough employed in combating prostration and blood stasis. The difficulties and prejudices to be overcome before it can be generally adopted in pneumonia are so great that it is with some diffidence that one undertakes to break ground. Hydrotherapy has been so much the property of men who have prostituted medical science to the ends of mere personal profit that much of value has been lost to more conservative practitioners. No one who has once witnessed the splendid results of systematic cold bathing in typhoid fever would be willing to cut off from this resource in a severe case. In the same way in pneumonia the effect of hydrotherapy properly adapted to the condition of the patient would reduce mortality as much as in the case of typhoid fever. It can never be emphasized enough that the value of hydrotherapy extends far beyond the limits of the mere reduction of temperature. The effect is a general tonic to the nervous system, rehabilitating the heat-controlling forces of the body and restoring the tone of the circulation. To accomplish these results, the temperature and duration of the bath must be properly adapted to the case and the conditions present, but there is one element in the application of bathing that is of so much importance that one is almost tempted to speak of the treatment as tub rubbing instead of tub bathing. While in the bath the patient must be properly rubbed in every part of his body by a sufficient number of properly trained attendants. Without the rubbing properly carried out, the tub bathing in an acute disease is indeed the fearfully dangerous procedure that it is often supposed to be by those who have not given the subject mature consideration.

The Brand method of treating typhoid fever gives a standard—the bath of 65° F., the rubbing by strong attendants during the whole time of immersion, the immediate removal to a dry bed, the precautions that a patient should never be bathed when the feet are cold, and that cold feet after a bath should be treated by application of warmth.

Every man, before undertaking the treatment of disease by the application of cold water, would do well to follow a few cases of typhoid treated by this method. Then he would be in a position intelligently to depart from the set system, according to the demands of each case. Thus the bath may be advantageously modified by only half covering the patient, and trusting to the attendants to apply water to the part of the body not

covered. A very suggestive paper by Dr. F. Gundrum, of California, in the *Therapeutic Gazette* of last year, emphasizes the importance of hydrotherapy in pneumonia. He found that by placing a blanket in the bath under the patient the treatment was rendered less objectionable. He states that in his experience packs were found a useful adjunct when for any reason frequent baths were difficult to give, but whenever the temperature went above 103° F. he resorted to the baths. With all other writers, he emphasizes the fact that equal in value with the reduction of temperature is the general nervous stimulus of the cold water and the rubbing. The effect of cold water in health, as a refreshing and stimulating agent, needs to be remembered.

Without detriment to the treatment the baths may be commenced at a temperature of 80° or 90° F., and then while the patient is being thoroughly rubbed the temperature may be reduced by the addition of cold water. This lessens the shock somewhat with sensitive persons.

In the discussion of the hydrotherapy of pneumonia, curiously enough we come once more upon the old question of heat or cold in the treatment of disease, emphasizing once again the only possible answer to this dispute of two thousand years' standing—that there is good in both. The ground for belief is strong in the experience of every one of you that in pneumonia heat applied to the chest by poultices, hot-water coils, or other means, has a beneficial effect upon the morbid processes within the chest. It certainly benefits commencing œdema from whatever cause, and is said to hasten the cycle of the pneumonic processes. That heat is good I firmly believe; on the other hand, there is good authority from some of the best observers in the world that cold applied to the chest in pneumonia has also the power of influencing for good the course of the disease, cutting short the processes and hastening recovery. Thus between heat and cold we cannot decide absolutely, saying one is good and the other bad. It is even possible that there are times when the very hot bath might benefit a desperate case.

In the Maternity Hospital I have frequently studied the effect of such immersion in new-born children, in whom vitality was at a dangerously low ebb.

The effect of a properly adapted bath was beautifully shown in the case of a child of seven. The child had pneumonia with a very high temperature and rapid pulse. There was much venous stasis, and everything seemed to be going wrong. This child was put into a bath at a temperature of 90° F., and thoroughly rubbed for a period of about fifteen minutes. When the child was taken out of the tub and put back to bed the temperature had fallen, the breathing was quiet, the pulse improved, and the whole picture had changed. The bathing without the rubbing would not have accomplished any such result.

In a discussion in the section on general medicine in the New York Academy on the treatment of typhoid fever by cold bathing, the influence of the baths as a respiratory stimulant was dwelt upon by Dr. A. B. Ball. It would seem that in pneumonia this action should be advantageous. Its wonderful tonic effect upon the nervous system, equalizing the circulation and bringing about physical rest, has astonished every one who has had the opportunity of studying fever cases so treated. Increase in the secretion of urine, such as is a constant observation in fever patients who are taking baths, would suggest improved elimination of toxins.

The reports of the treatment of pneumonia in which bathing was used as a tonic and supportive measure, as opposed to merely antipyretic baths, are very meagre. Professor Bozzolo says: "After a considerable number of observations: (1) Such baths are well borne in severe cases; they never produce collapse. (2) They lower temperature rapidly and notably, and keep it down for a considerable length of time; they may be repeated every three hours. (3) The mortality per cent. among patients treated thus with cold bath is among the lowest recorded under any form of treatment." [1]

The fourth and last point in pneumonia is the circulation. Every thoughtful physician has a philosophy of his own that guides him in the choice of means of stimulation. The direct care of the heart is equal in importance to the attention to delirium and the destructive forces of high temperature. Every one who has watched a patient with pneumonia from the onset of the disease to a termination has felt that the heart was the organ upon which the brunt of the battle had fallen. There is no question of equal general importance or greater difficulty than that of heart stimulation. It is a problem to be approached with the utmost humility, because there are many points upon which it must honestly be confessed that definite facts are not known. The mechanism of the heart and circulation are admirably adapted to fulfil their functions. The heart has its wonderful nerve supply, both from the central nervous system and from the ganglia within itself. The blood-vessels are governed by the marvellous vasomotor system, with its millions of constrictors acting as a system of regulators whose perfection surpasses the comprehension of man. The automatic action of the respiratory and cardiac nervous centres also elude our complete understanding. In health the slightest mental or physical exertion is followed by an increased effort on the part of the heart and a corresponding deepening of respiration. When anything happens to cause obstruction to the breathing or circulation, the heart immediately responds with a large increase of labor to overcome the obstruction, and the lungs increase their activity to an even greater degree. Now, nature having provided this wonderful plan of increased activity to meet emergencies, the question of stimulation resolves into an inquiry as to whether we can by artificial stimulants supplement with advantage the natural stimulus that comes from the nervous system. We come face to face with the possibility of injudicious stimulation, or stimulation at the wrong time, which may exhaust the natural resources so that they will not respond at a more critical period. On the other hand, leaving stimulation, pure and simple, out of the question, can we not control the action of the heart and conserve its forces to calm the excessive stimulation of an excited nervous system, and in this way reserve the force required to tide over a critical period? In addition to stimulation and control, it would seem that nutrition of the heart was of great importance. Particular drugs cannot be discussed at much length. The best general plan of management of the heart in pneumonia is to conserve its forces early in the disease by the control of delirium by the use of a proper antipyretic but at the same time tonic system of bathing, and by the use of such drugs as will relax the general circulation and diminish the hyperactivity of the heart. Undoubtedly with all its disadvantages the aconite group of drugs affords very valuable properties.

The importance of the philosophical consideration that it is the right side of the heart instead of the left which is chiefly in danger of exhaustion seems to impress itself with difficulty upon the profession. Dr. Andrew H. Smith has for a long time advocated the study of the pulmonic second sound as a guide to prognosis. Still it is not perfectly clear that we have any means at hand by which we can stimulate one part rather than another, nor, indeed, with all that has been studied and written, is the mechanism of the

[1] Gazetta Medica Italiana, July 2, 1881.

circulation so well understood that we can proceed to a very great degree in the treatment of particular parts of it with confidence. After all is said, when we recall to mind the impression made upon us by a critical case of pneumonia at the critical period, it is of an effort to apply cardiac and pulmonary stimulants with the object of tiding our patient over. Before my mind is a patient surrounded by the paraphernalia of the sick-room and the anxious attendants, but more distinctly there stands out in my imagination a picture of a struggling heart and certain alkaloids, notably strychnine, atropine, digitalin, and cocaine, that must be applied hour by hour to keep this heart from failing in its task. After one has cared for a case like this, it is often difficult afterward to describe just what doses were given, as each was administered according to immediate indications. In Wood and Fitz's new text-book on practice, we find the following recommendation that appeals to our judgment of stimulation in a severe case, the drug to be given hypodermically if not well borne by the mouth: Strychnine, one-twentieth grain, every four hours, and cocaine, one-sixth grain, every four hours, alternating so that one or the other is given every two hours. The strychnine may be slowly increased to one-fourteenth grain and the cocaine to one-half grain. Dr. Wood thinks he has seen life saved by even larger doses. Certainly a well-thought-out and courageously applied plan of stimulation offers the only hope for critical cases.

Time compels the omission of the discussion of the place of alcohol, belladonna, nitroglycerin, and digitalis in pneumonia. Nor can the place of bleeding be touched upon, but these will doubtless be taken up in the discussion.

Faith in the value of hydrotherapy in pneumonia is more the gradual growth of time and thought than a belief founded upon any special line of experiment or the teaching of any single person. The literature, though curiously meagre considering its importance, is entirely favorable to the views expressed above. Many occasions arise in the course of pneumonia when a tub bath of moderate temperature, carried out with skilful rubbing, would benefit the patient more than a great deal of drug stimulation. To carry on such a method requires courage, apparatus, and skill. In advocating it at this time we can only hope to stimulate thought, with the desire that means may be found to adopt this important measure in practical medicine. When reason is convinced, no valuable addition to therapeutics must be discarded on account of apparent difficulty or pre-existing prejudice. It was my privilege to witness the introduction of the cold-bath treatment of typhoid fever into a large hospital, and I have listened to all the objections that will be raised again in the application of hydrotherapeutics to pneumonia, and yet we have all seen this method accepted by every one who has had the opportunity of observing cases under treatment.

Until an antitoxin is discovered, the treatment of pneumonia must be in its final analysis expectant, and, valuable though it may have been to review the various means by which the patient is protected from mortal injury by the disease and supported to resist it, still in the application of each and every one of these measures the judgment of the individual physician at the particular time must have influence greater than the voice of any authority. It is this quality of judgment that is found in its most excellent development in the general practitioner occupying the field a little removed from the atmosphere of theoretical teaching and extreme specialism. To such men it is a privilege and an advantage to bring the results of thought, study, and research, and from them I trust my conclusions may be reflected back with the additional light of well-digested experience.

IN THE TREATMENT OF APPENDICITIS, IS THE FREE USE OF THE KNIFE NECESSARY?[1]

BY G. H. BALLEKAY, M.D.,

PATERSON, N. J.,

FORMERLY SURGEON TO THE WOMAN'S HOSPITAL, NEWARK, N. J.; GYNÆCOLOGIST TO THE GENERAL HOSPITAL AND TO ST. JOSEPH'S HOSPITAL, OBSTETRICIAN TO THE MATERNITY HOSPITAL, PATERSON, N. J.; FELLOW OF THE BRITISH GYNÆCOLOGICAL SOCIETY.

MR. PRESIDENT AND GENTLEMEN: Some years ago I would have entered upon this discussion with a good deal of self-confidence; to-day I approach it with a great deal of self-mistrust, for I cannot help feeling that the more I see of appendicitis the less I know about it. I shall endeavor to confine my remarks to answering the question propounded by your committee, viz.: "In the treatment of appendicitis, is the present free use of the knife necessary?"

The question cannot be answered offhand for the reason that every case of appendicitis is a law unto itself; and while in one class of cases the free and early use of the knife is absolutely necessary, in the other class the use of the knife is unnecessary and therefore unjustifiable. At the outset it is important to bear in mind the different varieties of appendicitis actually met with in practice.

Appendicitis presents itself under five different forms, as follows: 1st. Acute perforative appendicitis with diffuse general peritonitis. 2d. Acute simple, catarrhal, or interstitial appendicitis with circumscribed fibrinous peritonitis. 3d. Acute perforative appendicitis with localized purulent peritonitis. 4th. Relapsing appendicitis. 5th. Recurrent appendicitis.

Of these the first, third, and fourth varieties are the most dangerous to life. Recurrent appendicitis is probably the chronic form of what was originally an attack of acute or subacute appendicitis with circumscribed plastic peritonitis. This at least is the conclusion at which I have arrived from the observation of the cases occurring in my own practice as well as those occurring in the practice of my hospital colleagues whose operations I have witnessed. In most cases of recurrent appendicitis it will be found that the original attack was not very severe. It lacked the profound abdominal shock, pinched countenance, lividity of surface, retracted abdomen, and early and persistent vomiting of acute perforative appendicitis with diffuse general peritonitis; it also lacked the high temperature and frequent but comparatively full pulse of acute perforative appendicitis with circumscribed purulent peritonitis. It was in fact a moderately acute or subacute appendicitis, catarrhal or interstitial, with localized fibrinous peritonitis.

After the subsidence of the acute symptoms the exudation is generally in great measure absorbed, leaving only a small, elongated, indurated mass in the region of the appendix, which can be easily felt for several weeks after the patient is convalescent.

The appendix as a rule remains adherent to whatever organ or structure it was in contact with at the time of the invasion. It is often bent upon itself; its walls are generally thickened and indurated, and its cavity is sometimes dilated, sometimes sacculated, and contains a thick mucus or caseous-like substance. Stercoral concretions are rarely found in the appendix in recurrent appendicitis, whereas I believe that they are almost a *sine qua non* of relapsing appendicitis. To my mind recurrent appendicitis is the analogue of catarrhal or interstitial salpingitis with limited pelvic peritonitis. The pathological changes are the same in both; the symptoms sometimes so closely resemble each other that right-sided salpingitis is sometimes mistaken for appendicitis and *vice versa*. But owing

[1] Read at the annual meeting of the New Jersey State Medical Society, June 23, 1897.

to the reflex intestinal disturbances set up by a diseased and adherent appendix, its removal may be necessary for pathological changes which would hardly justify a resort to salpingotomy. The limits of this discussion will not permit me to enter in detail upon the pathological changes which occur in the various forms of appendicitis. But as a proper understanding of the clinical differences which present themselves to the observation of the intelligent practitioner can be obtained only through a clear idea of the pathological changes taking place in the appendix and adjacent structures, I shall briefly pass in review the morbid processes peculiar to each of the varieties above enumerated.

Our knowledge of the pathology of appendicitis has been derived rather from the observations of practical surgeons in the operating-room than from those of pathologists on the post-mortem table. To American surgeons is due the credit of having evolved the true pathology of the appendix. Their operations, often undertaken within a few hours after the manifestation of symptoms, enabled them to appreciate the structural changes which characterized the early stages of appendicitis, whereas the older writers could describe only the advanced and complicated morbid processes observed after death. American physicians have also contributed largely to our knowledge of this subject; and prominent among these is Reginald Fitz, of Boston. It must not be forgotten, however, that to Mêlier, of France, we owe all that we know of the disease under consideration; for it was he who first brought order out of chaos and taught that the diseases previously described as typhlitis and perityphlitis were in reality appendicitis, as the morbid process always originated in the appendix. Before the publication of Mêlier's observations the appendix vermiformis was credited with being an organ of little or no importance, the lesions of which often passed unnoticed in the autopsy room. Therefore, all honor to the brilliant Frenchman to whom the medical profession and suffering humanity owe a debt of gratitude which can never be paid.

Whatever may be the results of perforative appendicitis, its cause is always the same, viz.: the penetration into, and impaction within, the cavity of the appendix of a foreign body—generally a stercoral concretion. Many foreign bodies have been found in the appendix; but all foreign bodies other than stercoral concretions are found in only a comparatively small number of cases of perforative appendicitis. When a hard foreign body of irregular shape penetrates into the cavity of the appendix it produces a condition of irritability of the gastro-intestinal tract which is accompanied by colicky abdominal pains and sometimes vomiting. This condition is exactly analogous to that which is produced by the impaction of a gall stone in the common bile duct or of a renal calculus in the ureter. And as those conditions are spoken of as biliary and renal colic, so this condition may properly be called appendicular colic. The signs and symptoms which characterize appendicular colic are abdominal pain, sometimes vomiting, tenderness over McBurney's point, and rigidity of the right rectus abdominis muscle. Under the influence of the contractions of the walls of the appendix the foreign body may be forced back into the cæcum and the symptoms may disappear as promptly as those of renal colic after the passage of the obstructing calculus into the bladder. But if the concretion remains tightly wedged between the opposing walls of the appendix, what happens? Well, two things happen: first, we have an obliteration of the orifice of communication between the appendix and cæcum; second, there results a compression of the walls of the appendix and consequently an interference with the circulation in the vessels contained in those walls. The obliteration of the orifice results in the accumulation of the products of the glandular secretion of the mucous lining of the appendix and distention of its cavity, while from the compression of the vessels results a diminution of the vitality of the organ. But the obstruction and compression are not sufficient in themselves to accomplish the process of ulceration and perforation; the intervention of a third factor is necessary to bring about destruction of the anatomical elements of the walls of the appendix. This third factor is found in the presence of large numbers of bacteria, which invade the tissues already weakened and devitalized by the interference with the blood supply, and complete the work of destruction.

When the process of ulceration and perforation is so rapid that nature has no time to throw up protective barriers of lymph around the appendix—between it and the general peritoneal cavity—the disease presents itself in its most deadly aspect. This variety of appendicitis is known as acute perforative appendicitis, and is always followed immediately by diffuse general septic peritonitis. In cases in which the process of ulceration goes on more slowly, an effusion of plastic lymph occurs which binds the appendix to contiguous structures and thus protects the general pertioneal cavity from the sudden extravasation of the contents of the diseased appendix. This effusion of lymph is the result of a circumscribed plastic peritonitis. As the destructive process in the walls of the appendix goes on, a focus of suppuration develops. The collection of pus surrounds the appendix, which occasionally forms a portion of the abscess wall. At times when the abscess is opened, the appendix is found lying loose in its cavity, having been entirely separated from the cæcum in the form of a slough. Cases are occasionally met with in which after the existence of well-marked evidences of appendicitis the symptoms gradually subside, to recur after an indefinite period of time. The second or third attack may result in the formation of an abscess which contains a stercoral concretion, and occasionally the débris of the sphacelated appendix. These are the cases which I would classify under the head of relapsing appendicitis. It would seem probable that in these cases the stercoral concretion—which is the real thorn in the flesh—excites the morbid process, which proceeds to a certain point and then becomes quiescent. Later, without any appreciable cause, the fire becomes rekindled and the disease goes on until gangrene and destruction of the appendix and abscess result. In the early stage of this class of cases there has been an effusion of plastic lymph which protects the general peritoneal cavity so long as the walls of the abscess do not give way and allow its contents to escape into the cavity of the peritoneum. When suppuration occurs, the location of the abscess will depend upon the position of the appendix at the moment of the attack. The normal position of the appendix varies in different individuals. While its upper portion is attached to the posterior and inner border of the caput coli, its free extremity seems to enjoy a considerable degree of liberty, and consequently cannot be expected to be found always in the same place. The result of a large number of autopsies shows that in a very large proportion of cases the appendix is in contact with the posterior surface of the cæcum and the cellular tissue of the iliac fossa. If perforation occurs in a case of this sort, the resulting abscess will be in the subperitoneal cellular tissue of the iliac region, and the collection of pus most easily reached at the outer margin of the cæcum. The appendix, if long, may dip down into the pelvis and may be adherent to the rectum, or, in the female, to the ovary, Fallopian tube, or broad ligament. It is sometimes found adherent to several loops

of small intestine high up in the abdomen. Should perforation and suppuration occur under such circumstances, the practitioner might easily be deceived as to the nature and origin of the resulting abscess. In acute catarrhal or interstitial appendicitis with limited plastic peritonitis the changes in the appendix consist in turgescence and thickening of its walls, and dilatation of its cavity with a viscid mucous or semi-purulent fluid. The contiguous coils of intestine are adherent to it and to each other. When of recent date these adhesions are easily broken down with the finger. This form of appendicitis usually terminates by resolution, the plastic effusion being gradually absorbed. But if the disease in the walls of the appendix is very extensive, subsequent attacks are likely to occur, constituting typical recurrent appendicitis. In acute perforative appendicitis the process of gangrene and ulceration of the appendix may go on so insidiously that no marked symptoms occur until perforation has actually taken place. This is most likely to occur in cases in which a stercoral concretion becomes impacted in the cavity of an appendix previously the seat of interstitial inflammation, resulting in a loss of sensibility of the organ.

Symptoms.—The symptoms of appendicitis vary with the type of the disease. In its most acute form perforative appendicitis presents the following symptoms: sudden acute abdominal pain, beginning perhaps in the right iliac fossa but rapidly spreading over the whole abdomen; the countenance is pinched; the surface cool and sometimes livid; the abdomen is retracted and the right rectus muscle rigid. Vomiting is an early and persistent symptom and is sometimes accompanied by singultus. The character of the vomiting differs from that accompanying the other forms of appendicitis. It is more frequent and persistent, and often resembles the vomiting due to intestinal obstruction. An obstinate constipation is often present. The pulse becomes frequent early in the attack. It may vary from 120 to 130, 140, or 150, and as a rule it is a pulse of low tension. The expression of the face, when not altered by the injudicious administration of opium, is indicative of abdominal shock. The facies, the pulse, and the vomiting are the three symptoms which enable us to recognize early this hyperacute form of perforative appendicitis. Tenderness on pressure over McBurney's point is as a rule much more marked than at any other point of the abdomen. The temperature may not be above normal in the early stage; at times it is subnormal, but when the peritonitis has become general it may rise to 102° or 103° F., although it generally keeps below 102° F. As the disease progresses, the abdomen becomes distended; the vomiting becomes almost incessant; the pulse more and more frequent, and finally imperceptible, and the patient sinks and dies from exhaustion and sepsis.

In perforative appendicitis with encysted purulent peritonitis the pulse may reach 120 or more at an early stage, and the temperature in the evening may exceed 104° F., especially in young subjects. There may be vomiting, but it is not persistent, and as a rule yields readily to intelligent medication and alimentation. Constipation if present yields to gentle laxatives or carefully administered enemata. The absence of persistent vomiting, obstinate constipation, frequent adynamic pulse, and pinched anxious countenance will serve to distinguish this from the hyperacute form of perforative appendicitis in the early stage. Tenderness over the region of the appendix and rigidity of the right rectus muscle are common to this and the other forms of appendicitis. As the disease progresses, a well-marked tumefaction develops in the neighborhood of the appendix. This tumefaction is due to the presence of pus, and may continue to increase until the abscess bursts into the peritoneal cavity or elsewhere, unless the surgeon intervenes.

In catarrhal or interstitial appendicitis with limited plastic peritonitis the pulse is never very frequent and the temperature rarely goes above 102° F. The morning temperature is generally below 100° F. The pulse rarely reaches 110. The expression of the countenance is good. There may be tenderness over the appendix, and there generally is more or less abdominal pain; but the pain is rarely very severe. Rigidity of the right rectus is generally present. After a few days a greater or less tumefaction in the region of the appendix develops, due to the agglutination of coils of small intestine to the appendix by fibrinous exudation.

Treatment.—The first indication in the treatment of appendicitis is rest. The patient should be put in bed and closely watched in order to determine early the true nature of the case. No food, except some form of animal broth, should be given. Anodynes should not be administered, as they tend to mask the symptoms and create doubt in the mind of the practitioner as to the form of disease that he is dealing with. It is of vital importance that the type of the disease should be recognized at the earliest possible moment, for upon a correct appreciation of the nature of the case the success of the treatment depends. If the case prove to be one of acute perforative appendicitis with incipient diffuse general peritonitis, the abdomen should be opened immediately in the median line, the appendix excised, the abdominal cavity thoroughly flushed with hot saline solution, a glass drainage tube inserted, and the wound closed. Drainage is absolutely necessary in these cases, as the peritonitis is always septic. In perforative appendicitis with encysted purulent peritonitis, suppuration rarely occurs before the fifth day, and rupture of the resultant abscess into the peritoneum seldom takes place before the ninth day. The rapidity of the suppuration process bears a direct relation to the severity of the general symptoms—the more severe the general symptoms the earlier the formation of pus. If the temperature reaches 104° F. every evening for several successive days and does not fall below 102° F. in the morning, while the pulse keeps at about 120 and there is some tumefaction in the region of the appendix, suppuration as early as the fifth day is probable, and operation should not be deferred beyond the morning of the seventh day. If the evening temperature does not exceed 103° F., and the morning temperature 101° F., the pulse varying from 104 to 116 and the local swelling not increasing, operation may be safely deferred until the ninth day. Exceptions to this rule will be rare. If from the sixth to the ninth day there is some improvement in the general symptoms but no improvement in the local signs, or, on the contrary, an increase in the local swelling, the surgeon should not be deceived by the apparent improvement; he should proceed to operate without delay.

Acute Catarrhal Appendicitis.—Cases of acute catarrhal or interstitial appendicitis with circumscribed plastic peritonitis do not call for operative interference. Such cases are fatal only through the officiousness of the doctor. They probably constitute forty per cent. of all the cases of appendicitis met with in practice.

Recurrent appendicitis is sometimes associated with a chronic catarrhal inflammation of the lower bowel, which is as often the cause of the patient's discomfort or suffering as is the diseased appendix. This condition calls for intelligent medical treatment. But when the recurrent attacks are plainly traceable to the diseased condition of the appendix, its removal is not only justifiable but imperative. In conclusion I would state that the treatment of appendicitis does not belong exclusively to either the physician or surgeon. The

former is too prone to procrastinate and his procrastination may be paid for by the patient with his life. The latter has too great a tendency to resort immediately to his knife, which is often unnecessary. Let the physician call the surgeon early and place upon him the responsibility of deciding when to operate, but let the surgeon appreciate the fact that he is not called merely as an operator, that it is to his judgment, not to his scalpel, that the physician appeals.

Progress of Medical Science.

Carcinoma of the Breast in a Child.—Dr. Blodgett (*Boston Medical and Surgical Journal*, June 17, 1897) has reported the case of a youth, born of healthy parents free from all suspicion of malignant heredity. The father had been at times grossly intemperate. Up to the age of twelve years the boy presented no appearance of glandular or other disease, but soon after this time a swelling was noticed in the left breast, beneath and attached to the nipple, which was slightly reddened and harder than its fellow. The swelling and induration gradually increased in size during the succeeding months, and the skin became more extensively adherent. Surgical removal of the breast was advised, assented to, and effected. The growth presented on microscopical examination the typical structure of carcinoma, and had invaded all visible glandular tissue of the breast. The wound healed by first intention, and there had been no recurrence or metastasis at the end of five years.

Chronic Diarrhœa Due to Senile Degeneration of the Intestinal Walls.—Duprey (*The Lancet*, May 1, 1897) reports a case of chronic diarrhœa in a woman, fifty-six years old, in which he believed there existed degeneration of the intestinal walls, in consequence of senile changes. During a period of nine months the patient had suffered from four attacks of diarrhœa, each of which was more severe than the preceding one. In the last of these the temperature reached 101.2° F. and the pulse 84. The area of cardiac percussion dulness was unchanged; the heart sounds were feeble, but the rhythm was not disturbed. Vision was impaired and there was well-marked arcus senilis in each eye. The tongue was slightly furred and the patient retched often and occasionally vomited. She also complained of pain in the abdomen, which was tender on pressure. Fluid evacuations were passed from the bowels at intervals of twenty minutes or half an hour. Ptomain poisoning being suspected, brandy and milk with soda water were directed, in conjunction with a mixture containing bismuth subcarbonate and nepenthe. During the next twenty-four hours the diarrhœa was less frequent, but symptoms of cardiac failure made their appearance, and death appeared imminent. Repeated attacks of fainting occurred, the skin became icy cold, the lips livid, and the pulse at the wrist scarcely perceptible. It was now learned that fainting fits had occurred also in the previous attacks. In view of the marked degeneration of the cornea, the dimness of vision, the failure of circulation, and the chronic diarrhœa, the intestinal symptoms were attributed to degeneration resulting from senile changes. The treatment consisted further in the application of artificial warmth and the administration of five drops of tincture of digitalis and twenty drops of spirit of nitrous ether every four hours. Improvement at once set in and progressed to eventual recovery.

Meningitis and Typhoid Fever.—According to Dr. Kuehnan the disproportion between the cerebral symptoms in typhoid fever and the morbid lesions found in the nervous system have long attracted attention, and these pseudomeningeal symptoms are well known to experienced observers. Purulent meningitis has occasionally been seen in enteric fever. It has been put down as a mixed infection due to pyogenic micro-organisms, but it has been shown that the typhoid bacillus has pyogenic properties, and can produce this purulent meningitis. The author relates a severe case of enteric fever in a man, aged thirty-two, accompanied by hemorrhage and complicated by purulent meningitis. A bacteriological examination of the blood during life showed colonies of the typhoid bacillus. The cerebral symptoms did not appear until the thirty-second or thirty-third day of the disease. The patient rapidly became somnolent, the pulse irregular, and the urine and fæces were passed unconsciously. The pupils were equal, but reacted sluggishly. There was slight retraction of the head, but no optic neuritis. Death occurred on the thirty-sixth day in profound coma. The typhoid ulcers were nearly all in process of healing. Numerous typhoid bacilli were still present in Peyer's patches. There were slight microscopic changes in the renal epithelium. After the removal of the dura mater the convolutions were seen to be covered with purulent exudation. The pus was intimately connected with the pia mater. The presence of the typhoid bacillus in the mesenteric glands, spleen, and exudation over the convexity as well as at the base of the brain was proved bacteriologically. Here the purulent meningitis was a metastasis of the typhoid bacillus. The bacillus had penetrated into the blood, as shown by the bacteriological examination made during life, and had settled down by predilection in the membranes of the brain.—*Berliner klinische Wochenschrift.*

Extra-Uterine Pregnancy.—From a study on this subject by Dr. Chaput the following conclusions are announced: (1) the differential diagnosis between hæmatocele and pyosalpinx is usually difficult; (2) non-ruptured extra-uterine pregnancy before the fifth month can only be suspected; (3) in extra-uterine pregnancy complicated by non-encysted hemorrhage surgeons are unanimous as to the proper treatment being immediate laparotomy; (4) in encysted hæmatocele or effusion the choice lies between (*a*) laparotomy and (*b*) vaginal incision. The latter is far from being free from danger, and the author always performed laparotomy if hæmatocele resisted ordinary medical treatment. Even if it is first discovered on making a vaginal hysterectomy or puncture he would perform laparotomy, which makes it possible to take away the ovum and placenta and stop bleeding. In discussing these propositions Dr. Bouilly thought that in any case of extra-uterine pregnancy one had to do with an abdominal tumor which indicated laparotomy. Laparotomy is also indicated when sudden alarming symptoms make one suspect rupture of extra-uterine pregnancy. The symptoms of hæmatocele from rupture of extra-uterine pregnancy usually make the diagnosis easy; suppression of menses, suddenness of onset of symptoms, more or less peritonitis, and development of tumor in Douglas' pouch. Incision through the posterior cul-de-sac is the best treatment. Bouilly had operated in thirteen cases with the best results. Dr. Tuffier thought the diagnosis of rupture by no means easy. Out of four cases seen by him he mistook the first for acute peritonitis from perforation; in the second no diagnosis was made. He agreed with Bouilly that incision through the posterior cul-de-sac was the best treatment of simple or suppurating hæmatocele. Reynier and Terrier, however, would limit vaginal incision to septic cases, performing laparotomy in all recent ones, which allows the operator to see what he is doing, and to remove diseased appendages if necessary.—*La Semaine Médicale.*

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, August 14, 1897.

THE EFFECT OF CHLOROFORM UPON THE VITAL FUNCTIONS.

THE action of anæsthetics has ever been a favorite field of investigation by physiologists, and of late years many laudable attempts have been made to clear up the doubtful points involved. Notwithstanding these attempts, the question as to whether in cases of death by chloroform the respiration or the heart stops first is still an open one. The two Hyderabad commissions both came to the decision that in every case in which chloroform was pushed respiration stopped before the heart did. *The Lancet* special commission to investigate the matter from a clinical standpoint found, out of five hundred and six fatal cases, that the heart failed first in one hundred and forty-three, respiration first in fifty-nine, both together in forty-six; no note in two hundred and eleven. Therefore the conclusion arrived at bears out the view that in a large majority of cases death is due to syncope, so far as the clinical evidence can decide one way or the other. Dr. Hobart A. Hare (*Gaillard's Medical Journal*, June, 1897) is inclined to adhere to the belief held years ago, that both the respiration and the pulse need watching. He says: "As with other discussions in medicine, the truth of the question as to whether chloroform causes death by respiratory failure or by cardiac failure lies, as it were, half between the two antagonistic forces; and, further than this, the somewhat startling statement may be made that it is not directly due in the majority of cases to either of these causes. On the contrary, the cause of death from chloroform is usually vasomotor depression. My conclusions, therefore, are that while chloroform in its general depressing power depresses all vital functions, it is the question of blood pressure which is most important." Mr. Leonard Hill says (*Treatment*, May 27, 1897): "The cause of chloroform collapse is, in all cases, a primary failure of the circulatory mechanism. It is secondarily that respiration fails, on account of the anæmia of the bulbar centres. That the cause of chloroform collapse is primarily due to failure of the circulation is contrary to the conclusions arrived at by the Hyderabad commission. Examining all the tracings taken by this commission, I have found that in them, although it is not so interpreted by the experimenters, the same typical fall of arterial pressure is recorded actually occurring before the cessation of respiration. Thus their own experimental evidence contradicts the conclusions arrived at by the workers on the commission."

There can be no doubt that, whatever may be the outcome of the discussion, it has already been clearly demonstrated that respiration is of the greatest importance in chloroform giving. In regard to the safety of different anæsthetics, the fact cannot be too strongly urged that the chief cause of danger rests with the administrator. The safest anæsthetic is dangerous in the hands of a careless administrator, whereas the most dangerous, when used by a skilful and competent man, is, considering all things, marvellously safe.

IS INSANITY INCREASING?

PUBLIC opinion has decided that this is a neurotic age and that insanity is ever on the increase. This general impression, however, appears to be erroneous, and the trouble is probably more relative than actual. Yet that there is an increase can hardly be denied. A hot and bitter discussion has been prevailing on the subject for many years in Great Britain, and still continues with undiminished vigor. The lunacy departments there hold that the increase is only apparent, while those taking the opposite view contend that the increase is only too real. Regarding the question from a statistical point of view alone, the conclusion arrived at by most persons would be that the latter are right, but, as an old-time Glasgow professor was in the habit of telling his class, "Statistics are like sausages. It all depends on the old woman who makes them." In the *Westminster Review* for May is a slashing article attacking the arguments of the lunacy commissioners which they bring forward in support of their contention that the increase is only apparent. The writer of this article says that there is a real substantial and progressive increase, and backs up his words with figures. In 1862 in England there were 2.02 lunatics in every 10,000 of population; in 1895 there were 3.15. In 1862 where there were 1.36 in every 10,000 of the population; in 1895 there were 3.96. In 1862 in Scotland there were 2.01 lunatics in every 10,000 of the population; in 1895 there were 3.39. Figures so startling as these will take a great deal of explaining away, but to a large extent they are misleading. Statistics in lunacy must be dealt with very broadly and cautiously. One reason for the great increase in the population of hospitals for the insane is the fact that lunatics are looked upon with different eyes than formerly. In the early part of the century insanity was regarded with horror or scorn, and with little feeling of pity or sympathy. The truth that it was a disease possible to cure had not entered men's minds. An asylum was a prison, the inmates of which were treated more harshly than criminals; now that asylums are recognized as hospitals, they contain inmates who formerly were not counted as lunatics. The advance in England in the number of the insane has been almost wholly in the pauper class, and is doubtless due to the improved accommodation and treatment and the consequent enhanced appreciation of the benefits of being

an inmate of a hospital. This state of affairs applies also to this country. The accumulation of chronic cases is another fruitful cause of increase, and it must not be overlooked that the accumulation of chronic cases is inevitable at a hospital for the insane as differing from a general hospital, because at any insane asylum all the incurables, or nearly all, have to be kept as permanent patients. Under the modern system, too, the rate of mortality is very much less. When all that is to be said has been said to minimize as much as possible this increase, it is useless to pretend that there has been no real increase whatever. It is certainly not so great as statistics without necessary explanations and the alarmists would lead us to suppose; still the fact that there is some increase is more or less self-evident.

THE NEED OF A HOME FOR CONVALESCENTS.

The charity which would commend itself with greatest force to physicians and intelligent laymen is an institution which would provide a shelter for convalescents, and for persons not ill enough to secure hospital care yet not well enough to compete with the hard conditions of life in a large city.

There is not a physician in New York who has not met with poor persons too ill to look after themselves, and yet not proper hospital cases. With a few weeks' rest under proper supervision these unfortunates could be restored to a life of usefulness. In the same way discharged hospital patients, freed from disease but yet too weak to take up their usual burdens, could be rehabilitated.

We commend this idea to the thoughtful and practical philanthropist. No institution adequate for the real necessities of the situation is now in existence in this city, but the value of such a one would be immense. It would fill the great gaps beyond the reach of the hospitals. It would materially lessen pauperism, and bring back to independence and vigor thousands who now drift annually into helplessness.

Russian Congress of Syphilography.—A congress to arrest the spread of syphilis in Russia, recently summoned by the government, was attended by over five hundred persons, including physicians, teachers, professors, heads of penal and other institutions, inspectors of factories, and military and naval officers. Among the measures proposed were stricter supervision of the morals of the young and cultivation of outdoor sports; education of the public to the dangers of syphilis by popular illustrated lectures, pamphlets, etc.; the adoption of a uniform blank for recording all cases, and for annual reports to a central bureau; physical examination of prostitutes by female physicians, and also the examination of the men who visit them. Special measures for preventing the spread of syphilis among the innocent, which, as shown by Bulkley in his work on "Syphilis Insontium," is so common in Russia, were also recommended.

News of the Week.

The Cumberland County (N. J.) Medical Society convened at the Hotel Cumberland, July 13, 1897, with the president, Dr. H. W. Elmer, in the chair. Dr. Rulon Dare, of Deerfield, read a paper on "Serum Therapy," and Dr. D. H. Oliver reported on the advance in medicine. The society adjourned to meet the second Tuesday in October.

Dr. Joseph J. Kinyoun, of the Marine Hospital service, has been designated by the secretary of the treasury to represent this government at the international exposition on hygienic and sanitary service on shipboard, to be held in Brussels in September. He has also been appointed a delegate to the international leprosy conference, to be held in Berlin in October. While in Europe he will visit the several bacteriological laboratories on the continent, for the purpose of obtaining information for the use of the Marine Hospital service as to recent advances in the investigation of contagious diseases.

Collision with an Ambulance. — An ambulance from the Harlem Hospital was run into at Lexington Avenue and One Hundred and Twentieth Street on Tuesday last by an electric car. The ambulance surgeon received a scalp wound, and the driver was injured about the body.

The New Morgue.—The sinking fund commissioners have authorized the dock board to extend the pier at the foot of East Twenty-sixth Street to give additional space to the new morgue building. A resolution to the same effect was passed several months ago, but it was lost in the mayor's office and was not acted upon.

Mr. Christopher Heath, ex-president of the Royal College of Surgeons, is to deliver the second course of Lane lectures at San Francisco this year. There will be ten lectures on the following subjects: Two lectures on congenital malformations, two on diseases of the rectum, two on diseases of the jaws, one on diseases of the tongue, one on diseases of the joints, one on aneurism, and a concluding lecture entitled "A Century of Surgery." For accepting the invitation to deliver these lectures, Mr. Heath was bitterly assailed by some of his amiable colleagues in the Royal College, the charge being made that he had lowered the dignity of his profession by accepting the honorarium offered, although the latter will barely cover the expenses of the long journey.

The American Association for the Advancement of Science.—The forty-ninth annual meeting of this association was opened on Monday in Detroit by Vice-President McGee, of Washington, and continued in daily sessions until Friday.

To Keep Away Mosquitoes.—A resident of New Jersey, who has tried the prophylactic with signal success, writes that a mixture of one part of oil of sassafras in five parts of alcohol applied to the hands, neck, and other exposed parts, will effectually keep away the

most ferocious of mosquitoes. It is necessary to renew the application every two or three hours.

A Case of Supposed Superfœtation.—It was reported recently in Cleveland that a woman of that town had given birth to two children, one three months earlier than the other. At the time the first child was supposed to have been born, the woman was visiting in Connecticut. She returned with a girl baby which she declared to be her own. Three months later she gave birth to a boy. The husband and the attending physicians accepted the woman's story, and looked upon the case as particularly remarkable. On inquiry, however, it was found that the woman, who is out of her mind, had given birth to no child while in Connecticut, and it is now supposed that she stole the baby she brought home with her.

Bicycle Accidents.—During July, during about half of which it was raining and consequently few wheels were out, the newspapers reported forty-eight more or less serious accidents from bicycling. Most of the sufferers were those riding the wheel, but there were also many children run down while playing in the street. It is a favorite sport of these innocents to stand directly in the path of a wheelman and make faces at him, so that it is almost impossible at times to avoid an accident.

The American Jubilee Fund, which was started for the purpose of raising money to establish beds in perpetuity in the chief London hospitals, has been closed. The subscriptions exceed $21,500.

The Moscow Congress.—The preparations for the meeting in Moscow are proceeding with a slowness comparable to that of the railway trains and many other things in Russia. The preliminary programme, issued the latter part of July, announces that there will be but three general meetings, instead of five as first proposed. The Tsar will receive one member from each country, in order to fulfil his rôle of patron of the congress, but this reception will be held in St. Petersburg two days before the opening of the congress. The selection of the one person to be thus honored will be left with the national committee, instead of with the ambassador of each country, as was first announced. This will reduce the number of those taking part in the ceremony, for there will be time to appoint representatives from European countries only. The town council of Moscow was asked to entertain the members of the congress, but instead of doing so decided to establish a triennial prize for the best essay upon some subject connected with public health or epidemiology. Some twenty members will be put up at the Maison des Cavaliers, one of the official residences in the Kremlin, as guests of the Tsar, but it is not stated how these lucky twenty will be selected. The preliminary programme contains the titles of nearly one thousand papers which it is proposed to inflict upon the members of the various sections.

Professor Max Joseph Oertel, of Munich, died on July 13th. He was born in Dillingen, Bavaria, March 20, 1835. Early in his medical life he turned his attention to respiratory diseases, and was appointed to the chair of laryngology in Munich in 1867. He was especially occupied for a time with the study of diphtheria, upon which he wrote an article in Ziemssen's "Cyclopædia," and always claimed that he was the first to discover the bacillus of Klebs-Loeffler. His classical work on the pathogenesis of diphtheria was published in 1887. About 1870 he began to suffer from heart trouble, accompanied by albuminuria, marked circulatory disturbances, œdema, and obesity. After several years of orthodox but unsuccessful treatment, he restored himself to a state of practical health by means of a special diet and graduated exercises, which he afterward developed into a system followed in the various "Terrain-Curorte" which he established in Germany and Austria. This system he described fully in his articles on the treatment of circulatory disorders in Ziemssen's "Handbook of Therapeutics," on the milk cure in circulatory disturbances in the "Festschrift" in honor of Pettenkofer's jubilee in 1893, and on obesity in the "Twentieth Century Practice of Medicine"—the latter being his last contribution of importance to medical literature. He was an honorary member of many learned societies in Germany and other countries, and was the bearer of six decorations conferred upon him by the Emperor of Austria and various German rulers.

Philadelphia Hears of a Great Discovery, and at once puts it to practical use. "PHILADELPHIA, August 9th.—At the Polyclinic Hospital this afternoon the *x*-rays were used to locate a pin which was swallowed yesterday afternoon by Kate Kellie, five years of age. The child was playing with a spool containing four pins, and in pulling one out with her teeth it slipped down her throat."—Special Telegram to *The Sun.*

Obituary Notes.—DR. EUGENE FRANCIS SANGER, of Bangor, Me., died at his home in that city on July 24th, after an illness of several months. He was born in Waterville, Me., October 18, 1829. He was a graduate of Dartmouth College in the class of 1849, and then studied medicine in Philadelphia, receiving his M.D. degree from the Jefferson Medical College in 1853. After serving in the Marine Hospital at Chelsea and later on the staff of the Charity Hospital in this city, he went to Europe, studying in the hospitals in Edinburgh, London, and Paris. Upon returning to this country he began practice in Ellsworth, but soon established himself in Bangor. Immediately upon the breaking out of the civil war he joined the medical staff and served with distinction during the entire war, filling many important places of trust, and upon being mustered out at its close he was brevetted lieutenant-colonel for meritorious service. Returning home to Bangor, he commenced the practice of his profession in October, 1865, and continued there to the time of his death. In 1868 he was made examining surgeon of the pension bureau. He was made surgeon-general of Maine by Governor Chamberlain, and served seven years as surgeon to the State militia. He was president of the Maine Medical Association

in 1876. He was an honorary member of the Detroit Academy of Medicine and of the Baltimore Medical and Surgical Society; a member of the county and State medical societies, and of the American Medical Association; a member of the G. A. R. and the Loyal Legion.—Dr. Edwin Sprenkle died at Hanover, Pa., on August 4th, at the age of thirty-nine years, as a result of injuries received in being dragged and trampled on by his runaway horse. He was a graduate of Franklin and Marshall, and of the Jefferson Medical College in the class of 1884.—Dr. Albert F. E. Krog died suddenly at his home in this city on August 10th. He was a graduate of the New York University Medical School in the class of 1881.

Inspection of Chinese Laundries. — The health commissioner of St. Louis has issued an order for the inspection of all the Chinese laundries in that city. He says that many of the Chinamen are tuberculous, and that they carry tubercle bacilli in their mouths and squirt them on the clothes they are ironing, the latter thereby becoming carriers of contagion.

The Plague in China. — It is reported that the plague prevails in Canton, and the English residents in Hong-Kong are alarmed lest it break out in that city. Nothing has been done to put the Chinese quarter of Hong-Kong in a good sanitary condition, and it is feared if the plague once gains admission its ravages will be fearful.

Surgeons in Ordinary to the Prince of Wales.— Sir William MacCormac, president of the Royal College of Surgeons, and Alfred Downing Fripp, assistant surgeon to Guy's Hospital, have been appointed surgeons in ordinary to His Royal Highness. Mr. Fripp obtained his licentiate in the Royal College of Surgeons only eight years ago and was but recently appointed assistant surgeon to Guy's Hospital, and there is some grumbling that the Prince, now himself a fellow of the college, should not have selected one of his more aged colleagues.

An International Jenner Society.—It is proposed to organize among the members of the Moscow congress an International Jenner Society, the object of which will be the encouragement of vaccination and the collection and publication of facts and statistics in connection with smallpox and vaccination. Dr. Hubert, the secretary of the Russian Public Health Society, who has the matter of organization in charge, proposes the name Jennerianum for the new society.

Censure of Hospital Surgeons.—A boy shot himself accidentally last month through the palm of his left hand with a revolver. He was taken to one of the city hospitals, where the hand was dressed. The wound did not heal, however, and a few days later the boy was seized with convulsions. A private physician was then called and extracted a piece of wadding from the palm of the hand. The boy died from tetanus. An inquest was held, and the coroner charged the jury that the case was clearly one of criminal neglect on the part of the hospital authorities in not giving proper treatment to the boy. The jury returned a verdict that the boy came to his death by tetanus following a wound made by the wadding of a blank pistol cartridge, and they censured the surgeons at the hospital for failing to discover the wadding in probing the wound and for failing to remove the powder also contained in the wound.

Medical Society of the Missouri Valley.—The annual meeting of the society will be held at Council Bluffs, Iowa, Thursday, September 16, 1897. Titles of papers to be read should be sent to the secretary, Dr. Donald Macrae, Jr., not later than August 26th.

Antitoxin of Tetanus.—A case of tetanus in a colored man, resulting from a nail wound of the foot, has been placed under treatment at the Emergency Hospital at Washington, D. C., with antitoxin prepared in the United States army medical laboratory.

The Boston Medical Library has received the medical libraries of the late Drs. Edward Wigglesworth, of Boston, and William G. Wheeler, of Chelsea. The former is composed almost entirely of books and periodicals on dermatology, and contains nearly everything published on this subject up to a short time before the owner's death. The latter consists of books by early American writers, standard medical works, files of valuable periodicals, and a large collection of books and monographs on obstetrics and gynæcology.

Hot Weather in Italy.—The weather in all parts of Italy during July has been extremely hot, and to aggravate the sufferings of the inhabitants there is an ice famine, the price of this necessity having risen to $1.20 a hundredweight.

Beriberi has been discovered on board a Norwegian vessel recently arrived at Cork harbor from the west coast of Africa. Six of the crew were suffering from the disease and one had died on the voyage.

The Right to Practise Medicine in France.—The Paris correspondent of *The Lancet* writes that the French government has been asked to annul the by-law of two years' standing, under which foreign students desiring to study medicine in France were sent to the provincial universities. Previously to this by-law the foreign student was in a better position than the French student, because he was not compelled to serve three years in the army or to pass a matriculation examination of equal severity. As a set-off to this great advantage, foreign students were therefore drafted to the provincial centres instead of being permitted to work at the Faculté de Paris. But more recently a rule has come into force whereby the degree of doctor of medicine shall give the right of practice in France or French possessions only to such students as shall have passed the usual French preliminary examinations and have served three years in the army. Native talent is considered by the municipal council to be sufficiently protected now, and the prefect of the Seine has promised to communicate this view to the government. The commencement of the next November session will therefore probably see foreign students again inscribing their names at the Faculté de Paris, but the degree which they expect will not give them the right to practise in France unless they conform to the new regulations.

Clinical Department.

STRANGULATED UMBILICAL HERNIA—OPERATION AND RECOVERY.

By WILLIAM B. COLEY, M.D.,

NEW YORK,

ASSISTANT SURGEON TO THE HOSPITAL FOR RUPTURED AND CRIPPLED; ATTENDING SURGEON TO THE NEW YORK CANCER AND POST-GRADUATE HOSPITALS.

Inasmuch as successful operations for strangulated umbilical hernia are comparatively rare, the following clinical case may be of interest:

Mrs. S——, aged fifty-two, married, had had an umbilical hernia for twenty-two years, since the birth of her last child. The hernia had remained reducible until two years ago; since then it had slowly increased in size and had at times given rise to symptoms of incarceration. These attacks were accompanied by severe pain, with constipation, nausea, and vomiting, which sometimes obliged her to remain in bed for two or three days. The present attack began on April 21, 1897. There had been some pain at the site of the hernia the preceding day. The symptoms, however, became greatly intensified on the morning of the 21st, while she was attending to her household duties; vomiting soon began, became severe and frequent, and during the latter part of the day was greenish in color. She had one movement of the bowels in the morning. The pain greatly increased in severity, and at about four o'clock in the afternoon she was seen by Dr. George Peace, of Dover Plains, N. Y., who made the diagnosis of strangulated hernia. The tumor was about the size of a closed fist; the skin over the sac was discolored and very thin. The tumor on light percussion was dull; on heavy percussion showed an indistinct tympanitic note, which suggested bowel masked by omentum or liquid.

I first saw the patient on the train at Pauling, N. Y. At that time her pulse was 84; temperature, 99.5° F. She rode on the train eighty miles, during which time there was no vomiting, but considerable pain and much nausea. The tumor was exceedingly tender on pressure.

She was admitted to the Post-Graduate Hospital at 9 P.M., and immediately prepared for operation.

Operation was performed at 9:40 P.M., about ten hours after the beginning of strangulation, with ether as the anæsthetic. An incision through the skin and thin sac showed only a mass of discolored omentum which was adherent to the sac throughout, though most of the adhesions, especially those in the fundus of the sac, were of recent origin. There was little fluid present. On separating the omentum there appeared a knuckle of small intestine, about eight inches in length, badly congested, but which had not lost its glossy appearance. The bowel was completely enveloped in this mass of omentum, which really formed a second sac and could not be seen until an opening had been made in the omentum; on account of the thick layer of fat in the abdominal wall the ring was deeply seated, and, moreover, very narrow, making a very tight constriction. After the constricting ring had been cut, the bowel soon regained its color, and it was thought safe to replace it in the abdominal cavity. The entire mass of adherent omentum was then ligated in small sections with catgut and removed; the sac and skin pouch were likewise excised, and the wound was closed with three layers without drainage; kangaroo tendon was employed for the fascia. The time of operation was forty minutes. The pulse at the close ofthe operation was 78 and of excellent quality.

The subsequent history of the patient contained nothing worthy of note; recovery was absolutely uninterrupted; the wound healed by perfect primary union.

The mortality in strangulated umbilical hernia is still very high, varying between fifty and eighty per cent. The reason for this mortality lies, I think, in the fact that the patients are usually very stout women and very poor subjects for any serious operation. In addition, the hernia is usually complicated with a large mass of irreducible adherent omentum, the removal of which materially delays an operation which for its success is largely dependent on rapidity of execution.

HYDATIDIFORM MOLE.

By C. C. CRONKHITE, M.D.,

MARION, IND.

On February 16, 1897, I was called to attend Mrs. D——, primipara, twenty-two years of age, in what she supposed was confinement. On arrival I found her having pain and apparently in the first stage of labor. There was a slight discharge tinged with blood from the parturient canal. On palpation I found a large and doughy abdomen, quite firm at the lower portion of the womb. An outline of the child could not be made. Digital examination showed the cervical canal dilated to the size of a silver twenty-five-cent piece. The pains were increasing in severity. At 11 P.M. I was hastily called. The patient informed me that something had just passed during a severe pain. I found a large mass (at least half a gallon) and small particles continued to pass for three days. On the third day the patient was quite tympanitic. I used vaginal douches of hot carbolized water and placed turpentine stupes over the abdomen. After this there was a gradual and uninterrupted recovery. The patient thought herself at full time and believed that she had felt movement for several months. In September, 1896, she had a slight flow resembling menstruation. In October, 1896, she had pain in the womb and a small mass resembling a blood clot was expelled.

June 14, 1897

A TYPICAL CASE OF SCURVY IN A COUNTRY-BRED INFANT.

By CHARLES B. WARNER, M.D.,

PORT HENRY, N. Y.

The following case is of interest, as scurvy is such an extremely infrequent affection in this country. It also demonstrates unmistakably the danger of eliminating fresh milk from the dietary of tender infants. According to Dr. Northrup, in Starr's "American Text-Book of Diseases of Children," there have been in American practice only fifteen recently published cases of scurvy in children.

The subject of this report was born in May, 1894. Parents healthy and well-to-do; history of rachitis in maternal grandmother and two great-aunts. The child was weaned at twenty-two months, having been fed nothing besides mother's milk, except a well-known proprietary food prepared with a small quantity of cow's milk. This food was also the exclusive diet for eight months after weaning. For the next two months animal broths constituted the principal part of her bill of fare, not a drop of milk being given.

I was called to see her and found her suffering with lameness in the left leg. This condition increased rapidly. In a few days she was quite unable to walk, and carrying her or moving the limb caused intense pain. At night the pain in both legs was so great that she was deprived of sleep.

The legs were kept flexed, any attempt to straighten them causing her to cry out. The left tibia became a good deal enlarged in the lower third. A few days later the gums became sore and continued to grow worse until they became very much swollen, dark,

spongy, and bleeding. They could be separated from the teeth down to the alveolar process. The patient was fairly well nourished, but very petulant; the bowels were in good condition; the temperature was slightly elevated at times.

The treatment was antirheumatic for a few days, the true condition not being recognized immediately, followed by syrup of lactophosphate of lime, syrup of iodide of iron, solution of arsenite of potassium, quinine sulphate, bitter tonics with iron, and cod-liver oil inunctions—but to no avail.

A change of regimen was advised early in the case, fruit and milk being prescribed, but as the child disliked both they were not given. The proprietary food prepared with a small quantity of milk and animal broths constituted its *menu*.

On May 3d, the infant having been sick about three months, the situation was very clearly explained to the little girl's mother, and a radical change of diet was insisted upon, potatoes, fresh cow's milk, and orange juice being again prescribed. The juice of one orange was given each day and more milk was added to the food. Potatoes were not given. The effect was little less than magical. In three days the gums were wonderfully improved, and in five days were well. The improvement in the legs was almost as rapid, she being practically well in two weeks after commencing the orange juice.

To those unfamiliar with scurvy, it will seem either incredible or almost miraculous that a child could be restored from a constitutional disturbance so grave that death often results to perfect health, by the juice of five oranges.

SYMPHYSEOTOMY WITH AN UNUSUAL COMPLICATION.

By EDWIN B. CRAGIN, M.D.

The interest in the following case lies not so much in the operation as in the complication which interrupted the convalescence.

On February 25, 1895, the writer was called by Dr. H. S. Houghton, of this city, to see Mrs. V—— who had been in labor eighteen hours. Forceps had been tried, but their application proving very difficult they were abandoned.

Examination showed a narrow conjugate, a large caput, and no advance under powerful uterine contractions. This was her second labor. Her first occurred in 1893, and lasted forty-eight hours. After repeated applications of the forceps this first child had been delivered, but the head had been injured and the child lived but three days. The present condition seemed to indicate symphyseotomy, and as soon as preparations could be made this was performed with the able assistance of Drs. Houghton and Lyle. A male child weighing seven and a quarter pounds was then easily delivered with forceps.

The case progressed favorably. I saw the woman on March 17th, and told her she could sit up on the following day. That evening the husband, who was acting the part of nurse, gave her an enema. This was accompanied and followed by severe pain and the next day I was summoned in haste. I found a temperature of 103.5° F., pulse of 120, and abdomen distended, with dulness over the left inguinal region. Examination disclosed the fact that the husband in giving the enema had perforated the rectal wall and deposited the soapsuds in the retroperitoneal tissue. The finger passed easily along the false passage through and outside the rectum. I expected suppuration, but instead of that the soapsuds infusion was absorbed and in a week, *i.e.*, four weeks from the time of operation, the woman was able to sit up.

On April 25th I found the patient on the street, walking without difficulty and carrying her child.

May 20th I found her doing her washing. She could hop on either foot without difficulty and said she felt well and strong. The symphysis showed firm fibrous union with little if any motion. The true internal conjugate measured three and a fourth inches.

62 West Fiftieth Street.

A CASE OF PTOMAIN POISONING.

By J. A. O'NEILL, M.D.,

NEW ——

I called recently at a large machine shop to attend a workman who was said to be dying. I found him semiconscious, his face pale, lips and fingernails blue, pupils contracted, and pulse hardly perceptible. His respirations were sighing and occurred at alarmingly long intervals, yellow froth coming from his mouth with each expiration; involuntary defecation had also taken place.

I suspected opium poisoning but thought the patient too greatly depressed to stand an emetic, so I gave him a hypodermic injection of strychnine with a generous amount of brandy. Partly aroused by this he was soon able to drink some strong hot coffee and to answer questions. He said he had had a diarrhœa the night before but had taken no medicine or drug of any kind. He had eaten no breakfast but had drunk some milk from a tin canteen.

Knowing that in the early stages of putrefaction of nitrogenous bodies poisonous ptomains are produced, I changed my diagnosis from opium to tyrotoxicon poisoning. Ptomain poisoning frequently resembles that of the vegetable alkaloids, such as morphine, codeine, veratrine, etc.

A mention of this case seems timely during the present hot weather, and may aid some fellow practitioner to a diagnosis when confronted by similar ambiguous symptoms.

115 West Eighty-[illegible] Street.

MENSTRUATION AND EPILEPSY.

By D. T. MARSHALL, M.D.,

[illegible]

The following table was compiled from the histories of ten epileptic girls, to see whether the epileptic attacks were in any way influenced by the occurrence of the menstrual flow. The figures in the table are the totals for the months during which the observations were made, and do not indicate whether the attacks were more numerous immediately before or after the periods. Examination of the histories, however, would show that the attacks were about evenly distributed throughout the months, the periods apparently having no influence. Of thirty girls under observation but four gave any history of an aura. Of these one says she feels faint for a second before the attack. Another says she feels as though she were going to fall into a pit of fire.

Case Number.	Age.	Time under Observation, Months.	Total Number of Attacks.	Attacks during Menstrual Period.

Society Reports.

THE NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 3, 1897.

EDWARD G. JANEWAY, M.D., PRESIDENT, IN THE CHAIR.

Public Baths.—After a brief discussion the resolution offered at the last meeting to appoint a committee to urge on the city authorities the erection of public baths was adopted, and Drs. Simon Baruch, George Fowler, and Richard Van Santvoord were appointed on the committee.

Persistent Tachycardia with Digestive and Nervous Disorders.—DR. WILLIAM THOMSON read the paper upon this subject (see page 217).

DR. C. L. DANA said he had looked over his cases and found that he had a record of twenty-six with persistent tachycardia due to organic disease of the heart, eight to neurasthenia, four to melancholia, eight to Graves' disease, two to typhoid fever, two to paralysis agitans, and two to locomotor ataxia. Some of these cases gave a good many of the symptoms described in the paper, but he had found no case which he could not explain on some other ground than that presented by the writer. In some neurasthenic cases he thought the heart was small and weak, perhaps congenitally so, and the nerve force was small. Another class of cases was those of women nearing the menopause. The tachycardia in the melancholic cases was of psychical origin. Grippe sometimes left tachycardia that was very persistent, but he thought that was due to injury to the vagus nerve or to the ganglia of the heart. He could not understand how the alimentary tract, which is not a secreting gland, could be constantly throwing toxins into the system and thus causing persistent tachycardia.

DR. RICHARD VAN SANTVOORD said that the interpretation of the cases seemed to him in the main correct. It seemed that Graves' disease was somewhat analogous, probably due to a poison from the thyroid gland. He had been able to explain his cases on ground other than that of the writer. He had one case of tachycardia in which there were mild attacks of toxæmia for four years, but the tachycardia could be explained as neuralgic.

DR. JANEWAY said he thought the ground had been about covered. It was a question whether these cases should be considered as arising from toxæmia or from disturbance of nervous tone. He had had two cases which interested him especially, one in a lawyer, the other in a physician. Both had a very large output of urea and he thought the tachycardia might be due to that. He was not ready yet to express a positive opinion on the theory of toxæmia from the digestive tract.

DR. THOMSON said in conclusion that his subject disposed of the argument of Dr. Dana. He knew there were many cases of tachycardia due to the causes mentioned, but the paper dealt with tachycardia with pronounced gastric symptoms and not the ones referred to by Dr. Dana. It was possible by having patients eat bread and meat to prove that cases such as those mentioned could be due to auto-infection. The tachycardia could be induced by changing diet and reduced by returning to milk diet. He would also say that in many cases melancholia came from the alimentary tract.

No Smallpox in New York.—The last case of smallpox in this city was reported on July 14th, and the Board of Health announces that the epidemic is over.

MEDICAL SOCIETY OF NEW JERSEY.

One Hundred and Thirty-First Annual Meeting, Held at Atlantic City, June 22 and 23, 1897.

T. J. SMITH, M.D., OF BRIDGETON, PRESIDENT.

THE session was opened with prayer by REV. W. M. WHITE. The secretary, DR. WILLIAM PIERSON, called the roll. The mayor of the city, HON. F. P. STORY, then made a brief address, welcoming the society again to Atlantic City, where its meetings had been held several times, the last time five years ago. He was followed by DR. BOARDMAN REED, chairman of the committee of arrangements, who announced an excursion, reception, and entertainments. DR. H. R. BALDWIN read the report of the committee on business, by which it appeared that under the new bylaws several of the papers were to be in the nature of a *résumé* of therapeutics in different departments of medicine for the year, prepared by members of the standing committee. DR. READING announced that the photographer awaited the pleasure of the society, and DR. PIERSON hoped he would have to wait until he became as tired as the society had in the past. A number of gentlemen were invited to sit as corresponding members. DR. H. W. ELMER reported that the committee on ethics had not come to a decision in one case, but later reported for the committee, dismissing the charges. The report of the treasurer, DR. ALFRED MERCER, showed a deficiency of assessment to meet running expenses, and United States bonds had been deposited to secure a loan. Later a motion to sell one of the society's four $1,000 bonds to meet expenses in preference to borrowing was voted down, as a dangerous precedent in invading the permanent fund. The assessment for the coming year was made $2. DR. E. L. B. GODFREY read his report as corresponding secretary, which showed considerable correspondence in relation to appropriation for State laboratory, vivisection in the District of Columbia, with district societies, etc. THE PRESIDENT appointed on the auditing committee Drs. Baldwin, Hollister, and Blake, who found the treasurer's account correct. DR. H. G. TAYLOR reported that the committee on honorary membership had had no name submitted to it, whereupon DR. PIERSON nominated Dr. Pennington, of Newark, for honorary membership, his name to go to the committee for report next year.

Bovine Tuberculosis.—DR. J. W. STICKLER, of Orange, chairman of the committee on legislative action on bovine tuberculosis, stated in his report that the committee thought it could do something toward securing a more effective legislative measure for the eradication of bovine tuberculosis in the State if it were authorized to act with certain other bodies, including the State board of health and the dairy commission. On motion the committee was continued and authorized to act in conjunction with the bodies named.

State Laboratory at Princeton.—DR. D. M. SKINNER, chairman of a committee which had been appointed last year to go before the legislature to urge the passage of the bill appropriating money to the laboratory of bacteriology at Princeton, reported that the committee had been successful in its mission, and $3,000 had been appropriated.

Report of Standing Committee.—DR. H. W. ELMER read the report, which was supplemented later by reviews of the progress of medicine in its different branches by the other members of the committee. It appeared by Dr. Elmer's report that a local society existed in Atlantic City, called the Atlantic City Academy of Medicine. Most of the county societies held only two meetings during the year, one in the spring and one in the autumn. In some portions of the State

there had been a good deal of typhoid fever. The general death rate per thousand in Atlantic City had been only 6.5 per cent., which was extraordinarily low.

Expert Testimony.—Dr. William H. Iszard, in the last part of a paper reviewing the subject of expert testimony, pointed out the desirability of a change in the law, which seemed likely to take place in New York and some other States, making the medico-legal expert an officer of the court rather than an *ex-parte* witness for the side of the prosecution or defendant.

Surgery.—Dr. Charles Young, in a review of the surgery of the year, referred to Murphy's report of two cases of end-to-end suture after resection of large blood-vessels injured in continuity;[1] to a new mode of ligaturing which permitted removal of the ligature without cutting and which had been employed in the Woman's Hospital; to Stimson, on the use of saline injections in extreme shock; to Wyeth, on local anæsthesia by cocaine; to the report in *The Lancet* of a case of tetanus which recovered under mercuric biniodide; to the use of antistreptococcus serum; to articles on gunshot wounds of the head, wounds of the air passages, injuries of the liver in which exploratory laparotomy was recommended, blunt needle for ligation of liver vessels, use of catgut ligature. Articles on perforating gastric ulcer pointed out the necessity for operation. One operator had reported five cases, with four recoveries. One patient, operated upon fifty hours after perforation, had recovered. Surgery had been shown to be the only rational treatment of typhoid ulcer with perforation. The rules laid down by Shrady for operation in appendicitis were read. In the treatment of fractures Woolsey considered the ambulatory plan as ideal.

State Medicine and Hygiene. — Dr. Henry Mitchell, of Asbury Park, stated in his review of this department that many new facts were continuing to be brought out which had important bearing upon hygiene and State medicine. In laboratory work the department of bacteriology had been most rewarded. Mention was made of Koch's discovery in prevention of the rinderpest, of diphtheria antitoxin, of sero-diagnosis of typhoid fever, of the possibility of oysters conveying infectious germs, of the increasing use of formaldehyde in disinfection, of the aseptic-tank system of treating sewage, of the pasteurization or sterilization of milk, of the appointment of medical school inspectors, which he hoped would come to be done in New Jersey.

Diseases of Nose and Throat. — Dr. Fayette treated of this topic. He spoke of advantages of the forehead electric lamp over the head mirror, and of the fact that autoscopy seemed to be viewed with greater favor by some than was laryngoscopy. The *x*-ray gave promise of some utility in diagnosis of the upper air passages. Dr. French had been prosecuting laryngeal photography with success. The treatment of goitre with thyroid had shown good results in youth, but the likelihood of recovery from any mode of treatment was slight in adults. Relapses were the rule. The relation of ear disease to postnasal adenoids had received considerable attention. The indications for operation depended upon the mischief produced by the adenoids rather than upon their quantity. Mention was also made of the relation of the uric-acid diathesis to hay fever. A constantly increasing volume of testimony had been recorded in favor of the existence of this diathesis.

Eye and Ear.—Dr. Chambers, of Jersey City, presented a review of this department. He spoke of the use of formaldehyde as a disinfectant; of one author's observation of blennorrhœic ophthalmia in spite of the use of the Credé method; of the Roentgen rays in disclosing small pieces of metal in the lens; of the treatment of prolapse of the iris by excision if seen at once, tentatively if seen after a few days; of tinnitus aurium in ear affections; of surgery of the ear, of the sinuses, or of the brain in cases of abscess, etc.; of Tiffany's preference for chloroform anæsthesia in brain surgery. Buck he said had called attention to the connection of gout with diseases of the ear, and various other things.

President's Address.—Dr. T. J. Smith, of Bridgeton, chose for the subject of his address, "The Problem of Dependency." As a director in the New Jersey training-school for feeble-minded children, he had given a good deal of thought to this subject, and it had again been strongly forced upon his attention by the failure of the governor to approve the bill providing for an epileptic colony. The law of the survival of the fittest did not release us from our obligations to the dependent. Compassion, charity, and love were above natural law in the restricted sense. Compassion was not natural; it was supernatural. Besides, these people who required charity were the fruit of our civilization, which made it but just that those endowed with strength and wisdom should help the weak. Yet the problem of dependency, with the proper conception of its varied causes and results, had been a perplexing one since the inquiry, "Am I my brother's keeper?" was first propounded. The failing ranks of the human race were ever to be replaced with a certain proportion of the degenerate, the inefficient, and the vicious. Shall the stringent process of law or the gentler influence of benevolence prove to be more successful agency in dealing with such persons? Social reforms moved slowly. It was much easier to walk in the old ways than to search out new. True reform was accomplished by persistent effort wisely directed. We could not discharge our duty to those in want by simply flinging them a gift in passing. When the law of benevolence supplanted that of mere friendship, it had marked the transition from a pagan to a Christian civilization. The president then took up the subject of the care of epileptic dependents, and advocated the adoption of a method which had prevailed for years in France and Germany of caring for them in colonies, a method which had recently been put to a practical test in New York, at the Craig Epileptic Colony. It was shown that epileptics improved, that some of them were permanently cured at these colonies, that they became useful and contented in their several occupations and largely self-supporting. At present in New Jersey they crowded the asylums for the insane and the poorhouses, and created much alarm among other inmates when their paroxysms occurred. At the laboratory the pathology of the disease, about which we now knew little, could be studied. It was estimated that in New Jersey there were from two to three thousand epileptics, and in the United States one hundred and thirty-five thousand. The legislature had made a small appropriation for the starting of an epileptic colony, but the governor had vetoed the bill. It was necessary, therefore, that the society should continue its educational work.

Dr. Marsh moved that a committee of five be appointed to present the subject of establishing an epileptic colony before the legislature, if it thought best. The motion was adopted, but Dr. Marsh declined an appointment on the committee, because he had no positive views on the subject.

Some Important Points in the Treatment of Pneumonia.—Dr. L. F. Bishop read the paper (see page 228).

Foreign Bodies Found in the Stomach of an Insane Man.—Dr. B. D. Evans exhibited half a dozen spoons, over a dozen stones of various sizes, and as many other hard objects, which were found in the stomach of a man who had died recently of chronic

[1] Medical Record, January 16, 1897.

insanity in the asylum at Morris Plains. About four months before his death he had been detected swallowing the handle of a spoon, and then confessed having swallowed various objects with the intention of committing suicide, for he had been placed under guard for other attempts upon his life. There had been nothing to direct attention to his stomach until he was seen to swallow the spoon handle. Hard objects could be felt on palpation, but no operation was undertaken. It was only when closely questioned that he had admitted having a gnawing sensation in the stomach. A number of stones had passed by the anus. He died of dementia, and autopsy showed numerous stones, spoons, etc., in the stomach and intestine.

A Criticism of Modified Milk of Present Dairy Methods.—Dr. Richard C. Newton, of Montclair, read the paper. When we considered the fact that the science of lactology, if he might be allowed to coin a term, was only about a dozen years old, it gave promise of great things. It was likely that milk would come more and more into demand as a food product as time went on. The advance made in the subject of lactology the last few years had been remarkable, and, with discoveries likely soon to be made in bacteriological lines, promised to revolutionize many methods now in use in dairies. It must be admitted, however, that at present we could not base the feeding of infants upon our knowledge of the chemistry and bacteriology of milk. Often trial alone would determine whether the milk of a given animal would agree with an infant, or how it required to be modified. He had come to the conclusion some years ago, and experience had confirmed him in the opinion, that the sooner milk was fed to the infant after being taken from the udder the better, and the less it was shaken the better. Clinical illustrations were given. The author considered the various subjects of sterilization, pasteurization, alkalinity or acidity of milk, danger of infection, comparative value of milk from different animals for infants, etc.

In the Treatment of Appendicitis, is the Free Use of the Knife Necessary?—This was the subject for discussion decided upon at the last annual meeting. The discussion was opened by Dr. G. H. Balleray, of Paterson (see page 231).

Dr. H. R. Baldwin related clinical experience which led him to think that many cases of appendicitis recovered without operation. His treatment had been to move the bowels and to poultice outside and inside—flaxseed outside and Indian meal inside.

Dr. I. N. Quimby said that while he was fond of operating he really thought the physician should be first to take charge of cases of appendicitis. There was some disposition to substitute the knife for therapeutics, which he thought was a great mistake.

Dr. M. Lampson, of Jersey City, said the burning question to-day was when to operate, if at all. On the one hand there were surgeons, he believed, who recommended operation in every instance—if not at the moment yet at some time, perhaps between attacks. Then there were physicians who were too conservative and too slow to permit operation. It had been shown in the discussion that forty per cent. of all cases of appendicitis would recover even spontaneously, and some had claimed that as many as ninety per cent. would recover without operation. That suggested the question: Would the loss of life be greater if no operations were done? His own experience with operative interference had been rather unfortunate, he having lost three out of four cases last year.

Dr. P. A. Harris, of Paterson, recalled the teaching of Alonzo Clark with regard to peritonitis and its treatment by opium, and was inclined to think that many patients with appendicitis or conditions so diagnosticated would be better off with that treatment. If this treatment were not carried out the cases were more likely to require operation.

Dr. Newton defended two New York surgeons against the charge that they used the knife in all cases.

Dr. A. W. Sullivan was disposed to find the mush-and-poultice treatment applicable in most cases.

Dr. Barton, of Philadelphia, expressed his views at some length in favor of surgery, which he found indicated in many cases.

Dr. Ill believed that he operated in not more than one of half a dozen cases of appendicitis seen. He regretted very much that Dr. Harris had commended the opium treatment. It locked the bowel, masked the symptoms, and did nothing but mischief.

Dr. Reilly gave some personal experience.

Dr. Boardman Reed said they once called all cases typhlitis and perityphlitis, and later appendicitis. At one time he believed in operating in nearly all cases, but further experience had brought him to medium ground.

The discussion was continued by Dr. Rigg and closed by Dr. Balleray.

The following committee was appointed on the President's address on the founding of an epileptic colony: Drs. Barker, J. T. Smith, John W. Ward, B. D. Evans, and Shepherd.

Headaches, Auto-Intoxication a Factor.—Dr. Luther M. Halsey, of Williamstown, chose this as the subject of his address as third vice-president. The investigations of Bouchard, Ratchford, Haig, Sternberg, and others were reviewed, a few clinical cases were read, and the conclusion was arrived at that auto-infection had not a little to do with certain disturbances of the system, particularly nervous disturbances and headache. There could be no doubt that the authors named were working along lines where they were likely to discover important causes of disease.

A Successful Prize Essay.—The Fellows' Prize of $100 was awarded to Dr. George Bayles, of Orange, for an essay on antitoxin. An essay by Dr. Floyd Ewen received favorable mention.

Scarlet Fever Reproduced by Inoculation, and Some Important Facts Deduced Therefrom.—Dr. J. W. Stickler presented a brief statement of some experiments which he had been carrying out the past six years. He began with the view of developing an immunizing serum for scarlet fever. Instead of succeeding in this he had proven another fact of importance. The secretions were taken from the throat of a man ill with scarlet fever, the eruption having been present two days. As stated, the object was to discover an immunizing serum. The secretions were diluted with water, and also a part with carbolic acid, 1–600. Ten persons were inoculated, six of them infants, at one time, the needle being introduced only just under the cuticle, not into subcutaneous tissue. All developed typical scarlet fever. Fortunately all recovered. The average period of incubation was thirty-two hours; average time before vomiting, twelve hours; average temperature range, 99.22° F.; shortest time for desquamation, three days; longest, nine days. The experiments established these facts: 1. That the mucus of the throat and mouth contained with absolute certainty the contagium of scarlet fever. 2. That the early eruptive stage was exceedingly infective because of the discharges from the mouth and throat. The remaining conclusions referred to preventing the spread of the contagium, especially from the mouth and nose.

The Present Status of the Serum Treatment of Diphtheria.—Dr. Alexander McAllister, in presenting the present status of the serum, especially the antitoxin, treatment of diphtheria, pointed out that its

position was becoming constantly less assailable, and that antitoxin ought to be used in every case of diphtheria. In the pharyngeal type one should use one thousand units immediately on making the diagnosis; if the case was seen later or was of the croupous variety, he should give two thousand units. If the symptoms were not relieved, the dose should be repeated.

Four Types of Infantile Diarrhœa, and Indications for Treatment.—Dr. W. Edgar Darnell read the paper. In a concluding remark on treatment he said it was necessary to eliminate from the bowel the causes of the disturbance as far as possible, and adopt measures which would aid in restoring normal functions.

Rush Monument Committee.—The following committee was appointed on raising money for the Rush monument fund: Drs. William Elmer, E. L. B. Godfrey, W. J. Chandler, and Day.

Officers.—*President*, D. C. English; *First Vice-President*, C. R. P. Fisher; *Second Vice-President*, Luther M. Halsey; *Third Vice-President*, John J. H. Love, of Montclair; *Corresponding Secretary*, E. L. B. Godfrey; *Recording Secretary*, William Pierson; *Treasurer*, Alfred Mercer; *Standing Committee*, Stephen Pierson, Morris Iszard.

Place of next annual meeting, Asbury Park, June 28, 29, 30, 1898.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, December 9, 1896.

John Slade Ely, M.D., President.

The Formation of Giant Cells.—Dr. Anna W. Williams exhibited under the microscope a number of sections from the lung of a child. As these were obtained from a laboratory jar, labelled "miliary tuberculosis in a child," no history bearing on the condition was available. There were two pieces of lung—one from the neighborhood of the hilus, showing consolidation on gross examination; and the other, taken from the apex, showing a few scattered miliary tubercles. The sections exhibited were from the first portion. From the appearance of some of the giant cells, the speaker said she had been led to conclude that their mode of formation was more complicated than was generally supposed. The sections had been stained for tubercle bacilli, with positive results, and serial sections had been stained with hæmatoxylon and eosin. Under a low power a large number of giant cells are to be seen, many of them circular or oval, having an unusually regular outline, suggesting a wall, and the nuclei arranged more or less regularly about the periphery within this wall. Other cells are more irregular and less well defined. These cells are generally the centre of a smaller group of epithelioid cells. Under a high power the "wall" is found to be composed of elongated cells, with oval nuclei such as one sees in cross sections of small blood-vessels or lymph vessels. Within this wall are more oval nuclei and some spheroidal cells. The centre shows a granular and more or less homogeneous mass. The serial sections show that many of these giant cells are much elongated and branched. The branches are narrow and oblong, bounded by elongated nuclei, giving the appearance of a small vessel. The blood-vessels in these sections show little change except that the smaller ones in the vicinity of the tubercles have their walls infiltrated with small spheroidal cells. The bronchi show the changes of simple exudative inflammation. From these specimens it would seem reasonable to conclude that the principal infection occurs through the lymph channels, that, the lymphocyte taking up the tubercle bacilli and becoming agglutinated and degenerated, small particles of these degenerated masses pass to the smaller lymphatics, plugging them and causing a thrombus. The lymphocytes collect about the periphery of the vessel at this point, the endothelial cells increase, and necrosis extends from the centre. The observations made by Borrel on the formation of the giant cell in tuberculosis, as published in his article, "Tuberculose Pulmonaire Expérimentale,"[1] were interesting in this connection. He inoculated a pure culture of tubercle bacilli into the ear vein of rabbits, killing an animal immediately after the inoculation, and others every ten minutes, thirty minutes, three hours, fourteen hours, and then every twenty-four hours. Section of the hardened lungs were studied. He found that immediately after the inoculation there developed an intense polynuclear leucocytosis, most of the leucocytes containing bacilli. After a day this general polynuclear leucocytosis disappeared, and only a varying number of groups of these leucocytes containing bacilli remained in the blood-vessels. The evident decrease in the number of leucocytes was due to the fact that the blood stream carried some of them to other parts of the body, while others passed through the vessel wall into the alveoli of the lungs. On the third day the leucocytes containing bacilli in the blood-vessels showed degenerative changes, gradually breaking up and setting the bacilli free. As this last change was going on, a number of large mononuclear leucocytes formed about the periphery of the vessel at the place where the degenerated polynuclear leucocytes were grouped, inclosing the degenerated elements. Through the fusion of these mononuclear leucocytes with the central detritus, giant cells were formed. These Borrel called the intravascular giant cells. He did not say that he observed an increase in the connective-tissue cells of the blood-vessel wall, but that this takes place was very probable, especially when there are few bacilli, or when they are less virulent, or the individual predisposition to tuberculous infection was not great. In the present case only a few tubercle bacilli were found, and these were at the periphery of the more degenerated giant cells.

Dr. Henry Power said that he thought some of the appearances would lead to the conclusion stated by Dr. Williams regarding the formation of the giant cells. Such a conclusion could not be made positively, however, without more prolonged study of the specimens.

The President said that the specimens certainly indicated that some of the giant cells were formed in the manner claimed. In the cross sections many of the giant cells could be followed for a considerable distance, and with that regularity which would be observed if they had been formed in a channel. He saw no reason why giant cells should not be formed in this way.

Dr. Power asked what prevented the larger lymphatics from taking part in the same change.

The President replied that to get such a formation the lymphatic to be occluded must be rather small. If a small bit of cheesy matter should happen to gain lodgement, the arrangement would be eccentric. One would hardly expect that a large particle would be carried along in this way.

Constitutio Lymphatica.—Dr. James Ewing presented specimens hardened in alcohol from a case in which death occurred from chloroform narcosis. In connection with this case, he made some remarks on the subject of the "Constitutio Lymphatica."

Dr. Power recalled an autopsy in a case of Basedow's disease, in which the thymus gland was considerably enlarged. The subject was a woman, twenty-one years of age. The uterus and ovaries were undevel-

[1] Annales de l'Institut Pasteur, 1893.

oped, and the kidneys were lobulated. No other enlarged glands were found. He did not think that as yet we were justified in placing either the thyroid or the thymus glands among the lymphatic glands.

Dr. Ewing said he was not able to say just where the thymus and thyroid glands were to be classed. He thought a word ought to be said on the negative side of this subject. The lymphatic constitution did not seem to him as yet an established fact. Many victims of sudden death under chloroform had been previously subjected to severe tests of vitality, and had not succumbed. A fact in connection with reports from Germany which was of some importance, was the freedom with which chloroform is administered in that country. The diagnosis of constitutio lymphatica was accepted without comment in Vienna at the present day, and hence the condition should receive more attention here.

Fœtal Endocarditis.—Dr. Martha Wollstein presented a heart taken from a baby, six weeks old, who had been admitted to the Babies' Hospital. On admission there was a loud systolic cardiac murmur, heard with greatest intensity at a point just below the left nipple, but audible all over the chest. Cyanosis was present only just before death. The autopsy showed the heart to be enlarged, the left ventricle decidedly hypertrophied, the aortic orifice stenosed to about half its normal size, and the semilunar valves so agglutinated that there were only two flaps instead of three. All the other valves were normal.

The Diplococcus Intracellularis Meningitidis.—Dr. Wollstein also presented a brain from a boy who had been admitted to the hospital when five months old, after an illness of seven weeks. According to the history the child had been perfectly well up to the beginning of this last illness. The onset was sudden, and was marked by crying, vomiting, and the classical symptoms of meningitis. Three days before this the child had fallen out of bed on to the floor. On admission the child, although five months old, weighed only eight pounds eleven ounces. There was marked opisthotonos; the left patellar reflex was exaggerated; there was a spastic condition of all the muscles; the child was entirely blind; the pulse was 200 and irregular; there were no râles anywhere in the chest. The temperature just before death reached 105.4° F. There had not been any true convulsions, although there had been twitchings. The day before his death there was a hemorrhagic discharge from one ear. The autopsy revealed a thin, purulent exudate over the entire surface of the brain, most marked on the convexity. While removing the brain an abscess was opened into on the inferior surface of the cerebellum. It was about the size of a hazelnut. The pus was greenish and very viscid, and the convolutions were visibly flattened. Both lateral ventricles were filled with this same viscid pus. The third and fourth ventricles and their communication were also distended. Permission could not be obtained to remove the spinal cord, but the membranes, detached through the foramen magnum, were infiltrated. The lungs were not consolidated anywhere, but they were very hyperæmic and somewhat œdematous. A small infarction was found in the upper border of the left lower lobe. The liver was fatty. There were no other lesions. The petrous portions of both temporal bones were examined, and found to be normal. On making cover-glass smears from the pus and staining by Baumgarten's method, very few organisms were found, and these were all diplococci. They did not resemble the pneumococcus. They were not decolorized by Gram's stain. Cultures on glycerin agar from the ventricles and cerebellar abscess showed in twenty-four hours a grayish growth, which was much more abundant than would have been obtained from a pneumococcus culture at this time. On the second day there were larger colonies than would have been present from a pneumococcus culture. In neutral bouillon the growth was more luxuriant than a pneumococcus growth. A white mouse was given a subcutaneous injection of a pure bouillon culture. It remained well. After seven days it was killed, and the blood was found to be perfectly sterile. Dr. Wollstein concluded, therefore, that the organism in this case was the diplococcus intracellularis meningitidis described in 1887 by Weichselbaum. This organism was found by Jaeger to be longer lived than the diplococcus, and where chains were formed there were longitudinal lines of division. Weichselbaum described the diplococcus as decolorized by Gram's stain, but Jaeger had stated that the smears remained stained, although the sections were decolorized. It was very difficult to demonstrate the organism in sections. Anilin oil and gentian violet, followed by acetic acid and alcohol, constituted the best stain for the sections.

A Chondro-Epithelioma (?).—Dr. Henry Power presented a microscopical section of a tumor found in the subcutaneous tissue in front of the angle of the jaw in a girl of eighteen. The tumor had been there for some time, but had grown rapidly during the last two months. It was encapsulated and had a distinct hilum. It was easily removed. On section it was quite dense. There was a considerable quantity of cartilage in the tumor, both normal and degenerated, and scattered through this was a deposit resembling in some respects carcinoma. He presented the specimen for a diagnosis.

Dr. Ewing said that he had seen a tumor from the supraclavicular region which had presented an almost identical structure. The specimen presented suggested, of course, the possibility of its being an endothelioma.

The President also looked upon the specimen as probably an endothelioma.

Globular Thrombus in the Heart.—Dr. Harlow Brooks presented a tumor removed from the right auricle of the heart of a boy. When eight years old the child had had an attack of scarlatina. About two weeks ago there was found to be considerable œdema, and he was brought to the hospital. Examination of the urine showed evidence of acute nephritis. Physical examination of the chest showed mitral stenosis and a double aortic lesion. It was found necessary to tap the abdomen twice, and to drain the fluid from the lower extremities. Bacteriological examination of the urine and of the fluid taken from the abdomen was negative. At the autopsy the remarkable feature was the heart, which was very much dilated on the right side, while the left side was contracted and the aortic segments were much thickened. The mitral valves were very indistinct, and the papillary muscle had also become fused by an endocarditis. The right auricle contained the specimen presented—a mass which appeared to be a globular thrombus. It lay in the auricle perfectly free. In the fresh state its surface had presented a slightly papular appearance. A hasty reference to the literature seemed to indicate that this was a very rare condition. He found it difficult to understand how such a body could exist in the auricle during life without having been detected by physical examination. There were many areas of hemorrhagic infarctions in the lungs.

The President said that he had never seen just such a thrombus, although he recalled having seen a pedunculated thrombus presented to this society some years ago. The explanation of these cases, as offered by Dr. Osler, was that there was originally a thrombus with a slender pedicle, and that this had been broken off.

The society then went into executive session.

Stated Meeting, December 23, 1896.

JOHN SLADE ELY, M.D., PRESIDENT.

A Pancreatic Cyst.—DR. WARREN COLEMAN presented a pancreatic cyst removed from a woman, sixty years of age, who died of pulmonary tuberculosis in Bellevue Hospital, in the service of Dr. W. Gilman Thompson, through whose kindness he was permitted to report the case. Aside from the condition of the pancreas, the details of the autopsy were uninteresting in this connection. While removing the intestine a distinct prominence was noted in the pancreatic region between the stomach and transverse colon. It was found to be a cyst with fluid contents. The cyst, with the adjacent structures, including a portion of the duodenum, was removed. It was bilocular, consisting of a large and a smaller division, communicating by a large opening. A dense band of fibrous tissue extended across this opening. The cyst contained, but was not entirely filled by, a yellowish-brown, turbid liquid, in which were numerous small, shining, flat yellow crystals. The wall of the cyst consisted of dense fibrous tissue, with circumscribed thickenings on its inner surface. The total length of the cyst was 11.5 cm., the larger division measuring 8x10, and the smaller 3x6 cm. The thickness of the wall was 2.5 cm. On the inner side of the wall of the cyst toward the duodenum was a distinct papilla with a central opening, which admitted a filiform bougie. The bougie passed out into the duodenum, through the biliary papilla. The ductus communis choledochus joined the pancreatic duct in the wall of the duodenum. At first it appeared that all of the pancreatic tissue had disappeared, but on careful dissection it was found that several small masses were still present between the cyst and duodenum, and that there was a small, single mass at the extreme tip of the smaller division of the cyst. Sections taken from the wall of the larger and smaller divisions of the cyst show that there was no definite lining membrane. The wall was composed of dense fibrous tissue, which toward the cavity of the cyst, however, formed a more or less open meshwork, in which were chiefly small-round cells and a few larger, round, flattened cells. Young connective-tissue cells were also to be seen.

From these appearances it would seem that the cyst wall was adding to its thickness from within. The circumscribed thickenings on the inner surface of the larger division possessed essentially the same structure. They contained, however, numerous pigmented cells and a few giant cells, and were plentifully supplied with blood. The pigment, when tested with potassium ferrocyanide and dilute hydrochloric acid, failed to give the reaction for iron.

Albumin and mucus were present in abundance in the cyst contents. No sugar was found by Fehling's test, nor did Gmelin's test reveal the presence of any bile pigments. The crystals already mentioned were cholesterin. In addition, numerous small acicular crystals were present. A small number of round, flattened epithelioid cells were found. A moderate number of white and red blood cells were found, but they were supposed to have gained entrance on the knife and scissors used to open the cyst.

Experiments were undertaken to determine the physiological properties of the liquid. Three test tubes were filled with a dilute solution of boiled starch, and varying amounts of the cyst contents were added to them. They were put into an incubator for twenty-four hours, after which they were examined. The tube containing the greatest amount of cyst contents showed complete conversion of the starch into sugar, while the other two contained in addition to sugar some unaltered starch and erythrodextrin. The tests used were Fehling's solution and iodine. Unfortunately lack of time prevented examination for the presence of trypsin. The emulsifying ferment was not present. Fitz ("American Text-Book of Medicine") states, however, that in cysts of long standing one or more of the ferments may be absent, and, on the contrary, Boas and Jaksch believe that liquids possessing these physiological properties are not necessarily derived from the pancreas, since other pathological liquid accumulations might possess one or all of them.

Fitz also divides cysts of the pancreas into three classes, viz.: the retention cyst, the cystoma resembling cystomata of the ovary, and a form which appears to be on the border line between these two. Both of the former varieties might be multilocular. This author says that "in typical cases from dilatation the duct (of Wirsung) may be traced from the duodenum into the cavity of the cyst, and from the tail into the same cavity. At times the duodenal end of the duct is obliterated in the immediate vicinity of the cyst wall."

The speaker said that it was somewhat difficult to assign the cyst under consideration definitely to any one of the three classes. No evidence had been left of any cause of retention, and moreover in sections from the remaining portions of the pancreas there was no retention-dilatation of the ducts. Neither could the cyst be classed with the cystomata, because of the absence of a lining membrane. It was probable, therefore, that the cyst did not belong to any of the above varieties.

Referring to the etiology, he said that the cyst was evidently of long duration from the thickness and density of its wall. In the absence of definite evidence the question of the origin of the cyst must be a matter of conjecture. The most probable theory was that the cyst was of traumatic origin, though cysts arising in this region from traumatism were not, strictly speaking, pancreatic (Fitz), as a rule. The fact, however, that the remains of the pancreas were so widely separated, portions being at either end of the cyst, and the fact that the cyst cavity communicated with the duodenum through the usual channel would seem to show that originally the pancreas was of normal size and position. The retention theory was not tenable because of the absence of a calculus or a constriction in the duct between the cyst and duodenum.

The case was interesting also from another standpoint. The urine did not contain sugar, thus furnishing clinical confirmation of the fact established experimentally by von Mering, Minkowski, Hédon, and others, that if a small portion of the pancreas remain, whether in its normal relations or grafted under the skin, glycosuria did not occur. And this confirmation was all the more remarkable from the fact that sections from the remaining pancreatic tissue showed extensive degeneration. It was unfortunate that such symptoms of pancreatic disease as probably had been present could not have been noted. But the woman had been in the hospital only a day or two, and the pulmonary affection demanded the chief attention.

THE PRESIDENT said that a short time ago he had examined the contents of one of these cysts chemically, and had found neither the amylolytic or the proteolytic ferment present, and he had not detected any change in the starch after it had stood over night. He believed that the presence of the ferment was not at all constant in the contents of such cysts. It had just occurred to him that the cyst under consideration might possibly have been the result of a necrosis of the pancreas—as a secondary degeneration. He did not see why a cyst should not form in this way as well in the other ways already referred to. Such a change was occasionally seen in infarctions. Another possibility was an abscess formation.

Dr. Coleman replied that the objection to this theory was that there was an increase in the size of the cyst without any obstruction to the outflow of the contents. He had thought first that it might be of congenital origin, but had abandoned this idea because of the wide division between the parts, making it seem that the pancreas had originally been of normal size.

The society then adjourned.

Stated Meeting, February 10, 1897.

John Slade Ely, M.D., President.

A New Microtome.—Dr. Sidney Yankauer exhibited a new microtome, constructed on a novel plan, for which he claimed several advantages (see p. 250).

Dr. F. S. Mandelbaum said that he had used this microtome before it had been perfected, and had succeeded even then in making very good sections with it. With any new microtome one felt rather awkward at first. So far as he knew, the principles of its construction were entirely novel. The instrument was not quite so compact as some others. It had one drawback, *i.e.*, when one desires to use paraffin serial sections are usually wanted, and these could not be cut with this instrument.

The President said that as he had watched the action of the instrument it had seemed to him that it was not sufficiently rigid, and that it would be apt on this account to ride over the specimen at times. But even as at present constructed it apparently did very good work.

Dr. Yankauer said that this defect had been noticed in the original model, which had been made of wood. It was his intention in future instruments to have the bars made heavier.

A New Ganglion-Cell Stain.—Dr. E. S. Steese, present by invitation, exhibited several specimens under the microscope to illustrate a new combination ganglion-cell stain. The stain, he said, was essentially a modification of the Nissl stain, but consisted of two fluids instead of one. The method of its application was like that of the Nissl stain. The tissues should be cut into small pieces, and should be fixed, hardened, embedded, and cut in the usual manner. Corrosive sublimate and formalin, two per cent., and absolute alcohol seemed to be the best of the fixing solutions. If formalin were used, the specimen should be left in contact with it for at least forty-eight hours. The staining solution consists of two parts of a one-per-cent. aqueous solution of methyl blue and six parts of a saturated aqueous solution of fuchsin. After combining these two solutions, the mode of procedure is the same as with the Nissl stain. Only a few sections should be placed in a watchglass, two-thirds full of the fluid. This should be heated until vapor is noticed to come from the surface. It should then be set aside for not more than one minute to cool. The sections should next be immediately transferred to ninety-five-per-cent. alcohol. The differentiation and dehydration take place very rapidly. The specimens would become very white, generally in one or two minutes. When that is the case, they should be immediately transferred to some clearing solution, preferably oil of bergamot or oil of origanum. The latter he preferred. The mounting solution he had used was balsam, but damar also answered very well. The only advantage over the Nissl stain was that it seemed to give more character to the Nissl bodies, making them stain a deep purple instead of a greenish-blue. The neuraxons take a very pale violet, but they can be readily traced for a considerable distance, and within them the Nissl's bodies can be easily seen. The nuclei stain a pale violet. The nucleoli stain usually a rather brilliant red; the pigment granules also stain red. The surrounding sustentacular tissue remains absolutely colorless. The round cells, for the most part, stain red, although occasionally blue. The stain is also a very good one for cellular work, contrasting very well with eosin. Certain accidental observations had led him to think that it was possible that by proper dehydration the neuraxons could be stained a decided red.

Dr. Larkin asked if this were a combination of the two methods described by Nissl—the fuchsin and the methyl-blue method.

Dr. Steese replied that it might be called so, but Nissl used these two stains separately.

Dr. Larkin remarked that in clearing up the Nissl stain the oil of origanum did not work very well.

Thrombosis of the Pulmonary Artery; Advantages of Formalin as a Preservative of Gross Anatomical Specimens.—Dr. Larkin said that in preserving specimens in the gross for cabinet purposes, it was very desirable to keep the natural color, as far as possible. Alcohol, the time-honored preservative fluid, bleached the tissues, so that, for instance, a thrombus would turn white, and after a considerable time would be for the most part destroyed. If fresh specimens were dried in the air for an hour or two, and were then immersed in a two to five per cent. solution of formalin, and left in that for any convenient time less than a week, it would be found that they could be permanently preserved in ninety-five-per-cent. alcohol, and that the normal color of the structure of the organs and of the blood would be preserved. For microscopical use it was better to use a mixture of Müller's fluid and formalin. To illustrate the advantages of this method, Dr. Larkin exhibited a specimen showing thrombosis of the pulmonary artery. The color of the thrombus had been preserved quite well, and the endothelial lining of the pulmonary artery and the color of the lung had also been preserved.

Dr. Larkin then exhibited the dura mater from a case of

Chronic Hemorrhagic Pachymeningitis.—The patient was a German, who, for three weeks prior to admission to the hospital, had suffered continuously from headache and insomnia. For the last two days he had been semicomatose. On the afternoon of the day of admission he became comatose. He had previously complained of the sensation of a heavy weight on the head. After ten days of this coma he died. On opening the cranium the dura mater appeared very dark, and on removing it, it was found that there was a chronic pachymeningitis. The blood-vessels underneath the dura were very full of blood.

Dr. Larkin next presented specimens from a case of

Chronic Pachymeningitis, removed from a man, forty years old, who had been sick for five months previous to admission. One week before coming to the hospital he had had five fits. After entering the hospital he became semicomatose, and remained in that condition for about a week. He then had ten convulsions within twenty-four hours, after which he passed into coma and died at the end of six hours. At the autopsy the greater portion of the brain was found to be covered with a large effusion of blood. At the right temporo-sphenoidal lobe was a large depression, and just above this and near the occipital lobe a second depression. The corresponding dura mater on that side presented a large clot, which fitted accurately into the depression on the brain surface. The speaker remarked that a more careful clinical record of this case, made by a competent neurologist, would have probably added to our scanty knowledge of the functions of the temporo-sphenoidal lobe. The man was a syphilitic, and had well-marked endarteritis at the base of the brain and in the coronary arteries.

Dr. Larkin then presented specimens from a case of

Rupture of the Liver.—The patient, a young man of twenty-two, had been injured by being struck by a heavy box and thrown into an area. A depressed fracture of the skull caused his death a few hours later. In addition to the injuries to the skull, the autopsy revealed several quarts of fluid blood in the abdominal cavity, with some clots, and further examination showed a large rupture of the liver. There was no fracture of the ribs or of the vertebræ.

Discussion.—Dr. Mandelbaum said that after trying various methods for preserving anatomical specimens for museum purposes, he had recently adopted and could now recommend the following method: Fresh specimens should be subjected to formalin vapor for twenty-four hours; then, without coming in contact with water, they should be placed in ninety-five-per-cent. alcohol for twenty-four or forty-eight hours. They could then be transferred to a strong solution of acetate of potassium in equal parts of glycerin and water, and kept indefinitely in that solution. For exposing the specimens to the formalin vapor, it was convenient to use a large museum jar, in which was placed some absorbent cotton moistened with a forty-per-cent. solution of formalin. The alcohol could be used several times. The formalin at first bleaches the specimen slightly, but the alcohol restores the color and brings out the blood perfectly. After this the specimen does not undergo any further change. He had succeeded in preserving some specimens, which were in all respects as good as when perfectly fresh. Another plan was to place the specimen first in a solution of formalin, instead of exposing it to the vapor, but, according to his experience, this method was much inferior to the one first described.

Dr. J. S. Ely said that about a year ago a few specimens of intestine had been treated by this method—although he did not recall whether formalin solution or vapor had been used—and while the results obtained with it at the laboratory of the College of Physicians and Surgeons had been at first very satisfactory, the specimens had been noticed to deteriorate in the glycerin. Glycerin was always an objectionable fluid, for the reason that it made the specimens so transparent. He was also sceptical regarding the method just advocated by Dr. Larkin. Although the specimen presented looked well now, he felt pretty sure that in the course of six months a great deal of the color would have left the clot, and in a year or two the color would have almost entirely gone. He had preserved quite a number of specimens by placing them first in formalin, and then in strong alcohol. He had been delighted with the results at first, but the color had faded within two years. He had tried the plan of drying the surface before immersing the specimen in alcohol, and for a year or more the color had been well preserved, but it was now fading from the specimens so treated.

Dr. Larkin said that he had noticed that the potassium acetate also seemed to make the specimens very brittle, so that they could be handled with difficulty. The color of the specimen just exhibited by him had not faded perceptibly in two months.

The society then went into executive session.

Dyspepsia and Constipation in Children.—

℞ Sod. bicarb.,
Magnes. calcin .....āā 0.25 cgm.
Pulv. nuc. vom. 0.01

S. To take in a spoonful of sugar and water morning and night for ten days of each month.

The dose of nux vomica should not surpass half a centigram per day for each year of the child's age.—Comby.

Correspondence.

OUR LONDON LETTER.

(From our Special Correspondent.)

THE PRINCE OF WALES A DOCTOR—PARLIAMENT—BERIBERI—ARMY MEDICAL STAFF—DEATH FROM INFLAMMABLE HAIR WASH—BRITISH MEDICAL ASSOCIATION—HARROGATE NEW BATHS—THE LATE DR. CHANCE, SIR J. C. BUCKNILL, AND DR. H. THOMPSON.

London, July 30, 1897.

The Prince of Wales has accepted the honorary fellowship of the Royal College of Physicians, and so may be added to the short list of royal doctors. There are very few precedents for the honorary fellowship. As His Royal Highness will only be an ornamental fellow, the newspapers generally congratulate the venerable college on enrolling him.

There has been a further outbreak of beriberi at the Richmond Asylum, Dublin. In June there were ten patients still suffering from symptoms and the number rapidly increased to one hundred and twenty-four, though the type is said to be mild. A temporary hospital is to be erected. A new fully equipped asylum for twelve hundred patients is in course of erection, and it is expected a portion will be opened in about a year. It was stated in Parliament that the temporary buildings are being constructed to the satisfaction of the inspectors and with every care as to sanitation. No doubt the disease is fostered by the overcrowding which has for some time prevailed in the asylum.

The under secretary for war has given a rather evasive answer to a question as to whether it had been proposed to utilize students for ambulance work in the Soudan. He has also said that there are twenty-seven candidates for the army medical examination which is held to-day. How many will pass for the thirty vacancies? It is rumored that the twenty-seven will not turn up. Even if they do, the service will still be shamefully incomplete and the existing staff overworked.

A sad death from an inflammable hair wash gave rise to another question, to which the home secretary replied that the law as to petroleum was unsatisfactory, but he made no promise to attempt amendment.

This is the British Medical week, and the business part has been transacted in London as well as an extraordinary meeting to discuss resolutions as to defence, etc. The first was to require the council to obey the mandates of general meetings. An amendment was carried by sixty-two to forty-one, that as a report of a committee on the constitution is about to be issued it is premature and inexpedient to discuss the matter. Put as a substantive motion, the carried amendment was affirmed by seventy-one to fifty-five.

Another resolution to force the council to take up medical defence was proposed by Dr. Woods, who said the council had followed the example of the "heathen Chinee," referring the matter to the branches in the expectation they would negative the proposal. An amendment by Dr. Welsford, instructing the council to carry out the decision of the meeting of 1896, was carried by sixty-five to sixty-four. A division was demanded and resulted in a vote of eighty-nine for and eighty-eight against this. Later a resolution proposed by Dr. Myrtle requesting the council to take a plebiscite by reply cards was adopted by forty-eight to twenty-five.

On the balance sheet Mr. Lawson Tait made some good play about the costs in Kingsbury v. Hart, which were concealed among association expenses. Further, Mr. Tait exposed the practices of the editor and journal committee, and said the reference committee appointed by the council was improper and illegal.

Gold medals were presented to Sir W. Foster and Mr. Wheelhouse for their services to the association. The Stewart prize went to Dr. Sims Woodhead and the Middlemore prize to Dr. Hill Griffith.

Two members were expelled for their action in taking office at the Adelaide Hospital under circumstances of which you are aware.

The report of the constitution committee mentioned above was referred back to the council, with a request that it consult the branches and reappoint the committee. So the matter is staved off once more. Next year we meet at Edinburgh and Sir T. Grainger Stewart was appointed president-elect. Various votes of thanks and other formal business being over, we adjourned for the scientific work to Montreal.

On Saturday the Duke of Cambridge went to Harrogate and opened the new royal baths. These have been erected at a cost of some £120,000, and bring Harrogate to the front as a balneological centre, for she now offers the most sumptuous establishment of the kind in the country. A number of medical men from London went to the ceremony and still larger numbers from the surrounding district. Dr. Myrtle, whose name is closely associated with the spa, where he has lived long (I remember him between thirty and forty years) gave a magnificent reception in the winter garden to some eight hundred guests, to say nothing of his house party, where his hospitality was profuse. Nor were the other doctors behind in welcoming friends and visitors, though the *doyen* of the place naturally filled the most arduous part; but he is well qualified for the task. There can be little doubt that the new buildings will add to the fame of our great sulphur spa. An excellent feature of these splendid baths is that a patient can be wheeled into the dressing-rooms in a bath chair.

Frank Chance, M.B. Cantab., R.F.C.P., who died lately at Nice, aged seventy-one years, was a scholar as well as a doctor. He gained the Tyrwhitt Hebrew scholarship at Cambridge. His edition of Bernard's commentary on Job and new translation appeared in 1864, and was reissued with an appendix in 1884. His translation of Virchow's "Cellular Pathology" was published four years earlier. He was a member of the Old Testament revision committee, on which his scholarship was highly valued. He had retired from practice for several years.

Sir J. C. Bucknill, who died on the 20th, aged seventy-nine years, was a man of literary as well as scientific reputation. As early as 1857 his Sugden-prize essay appeared. The subject was "Unsoundness of Mind in Relation to Criminal Acts." From that time he was recognized as an authority. In conjunction with Dr. H. Tuke he wrote the well-known "Manual of Psychological Medicine." You will, no doubt, remember his "Notes on American Asylums," and his essays on the medical knowledge of Shakespeare and the mad persons depicted by the bard are of general interest. The *Asylum Journal*, which became the *Journal of Mental Science*, was founded and for a long time edited by Dr. Bucknill, and he contributed much to its pages. He was appointed lord chancellor's visitor in lunacy in 1862. He was called the father of the volunteers, for in 1852 he obtained permission of the government and enrolled the first regiment of rifle volunteers, and it was in recognition of this service as well as of his medical position that his knighthood was given him; but this token of approval was not offered until 1894, about twenty years after he had retired from official work and practice. Our governments are never in a hurry to recognize scientific men's work, even when they have contributed to the welfare of the country in other departments.

The death of another retired physician occurred last week, viz., H. Thompson, M.D. Cantab., 1853, consulting physician to the Middlesex Hospital, to which of course he had filled the staff appointment and where his chief life work was done. He was senior fellow of St. John's College, Cambridge, where he took his M.A. in 1841. He published some "Clinical Lectures and Cases with Commentaries" in 1880.

DECINORMAL SALT SOLUTION.

[illegible]

SIR: The term "normal" salt solution is almost universally employed in medical literature to designate a solution of sodium chloride of six parts to the thousand. I desire to call attention to the fact that this use of the term, strictly speaking, is erroneous, and that the designation "decinormal" is the proper one for a solution of salt of this strength.

In volumetric chemistry the term normal, as applied to solutions of reagents, has a very accurate and mathematically precise signification. A normal solution is "one containing in one thousand cubic centimetres an amount of the active constituent just sufficient to combine with or replace one gram of hydrogen" (Billings). For monobasic acids and their salts (such as sodium chloride) a normal solution is one in which the number of grams in the litre is equal to the molecular weight of the reagent. The molecular weight of sodium chloride is 58.37; a normal solution of sodium chloride is one containing 58.37 grams to the litre of water. A solution of one-tenth this strength, containing 5.837 grams to the litre, is a decinormal solution (see United States Pharmacopœia, 1890, and Sutton's "Volumetric Analysis").

The highest usefulness of the term "normal," as used in chemistry, can be secured only by its employment in its strict mathematical sense. To apply it to a solution of one-tenth normal strength is misleading, incorrect, and a violation of scientific precision.

WASHINGTON, D. C. J. B. NICHOLS, M.D.

HYDRAULIC DILATATION OF THE URETHRA.

[illegible]

SIR: I desire to add my testimony of approval of the hydraulic method of dilating the urethra, which was given in the issue of July 31st, by Dr. Rumer, of Davison, Mich.

The method is a good one, and has been practised by me for some time, being first suggested by a patient of mine. It is very efficient in many of the dilatable constrictions, and is, when it will answer, much to be preferred to the common method of using rubber or metallic sounds.

If properly practised it is surprising how much force can thus be exerted and to what capacity the urethra can thus be distended.

It is of great utility in washing out the bladder and urethra in gonorrhœa and other affections. In the treatment of gonorrhœa it has been my custom to have my patient thus distend the urethra and refill through a soft catheter, if convenient, attached to the faucet of a water pipe, when considerable external force or counterpressure can be exerted, care being taken to cut off the current when the bladder is full. Repeat the process of distending the urethra by forcing out the water as before, thereby thoroughly cleansing the bladder and urethra. Lastly, refill the bladder and follow with injections of whatever medicines it is intended to use. Let the water remain as long as desired, and force out as before. This leaves the bladder and urethra in a perfectly clean and aseptic condition.

In treating strictures, hydraulic counterpressure is obtained by attaching to the ordinary bath-tub faucet

a large-sized catheter, with central fenestra, introduced within the meatus and held firmly, and using long-continued pressure in the intractable cases.

By these two methods I have had most gratifying results.

J. B. TAULBEE, M.D.

MT. STERLING, KY.

New Instruments.

A NEW MICROTOME.

BY SIDNEY YANKAUER, M.D.,

NEW YORK

I DESIRE to exhibit to the society my new microtome,[1] which is not a modification of any old instrument, but is constructed on principles which, so far as I know, are novel in microtomes. In the Thoma instrument the knife moves in a slide, and the edge of the knife, considered as a line, describes in successive cuts the same plane. The specimen is moved up through this plane a distance represented by the thickness of the section to be cut. In my instrument the specimen remains stationary, but the plane in which the knife moves is continually lowered. The instrument consists of two parts—a stand and a sliding piece. The stand consists of a triangular piece of metal, across the base of which a plate of glass is fixed. Near this is a perforation containing a vertical rod. On top of the latter is the ordinary clamp for holding the specimen. At the apex of the triangle is a small elevation, *a*, and at the top of this elevation a hole, one-eighth of an inch in diameter and one-eighth of an inch deep. This hole is made hemispherical at the bottom, and is so placed that the bottom of the hole is in the same plane as the surface of the glass, so that if the surface of the glass were prolonged into a plane this would just touch the bottom of the hole. The sliding piece is made of a piece of metal, *e*, *f*, *g*, bent at a right angle, and having at its angle and at either end a perforation through which passes a screw. These three screws have the same sized screw threads, are pointed at the ends, and capped by small spheres, one-eighth of an inch in diameter. The screw at the end of the long arm of the sliding piece carries a plate on its upper end, which is divided into one hundred parts. This screw corresponds to the micrometer screw of the ordinary microtome. On this long arm of the sliding piece is the screw, *l*, by means of which the knife (*h*, Fig. 1) is fastened in such a position that it is parallel to the short arm of the sliding piece. As the screws are of the same length, the edge of the knife must be parallel to a line joining the points of the two screws on the short arm. The small sphere at the end of the micrometer screw fits into a little hole on the top of the elevation, and the two other spheres rest on the glass plate. By sliding the piece along the glass plate, the knife moves across the specimen. After being moved back again, the micrometer screw is rotated to the left. This lowers the end of the long arm of the sliding piece, and in so doing lowers the knife a certain distance. Then another cut is made, and the knife, being now in a lower position, must cut through the specimen at a lower point.

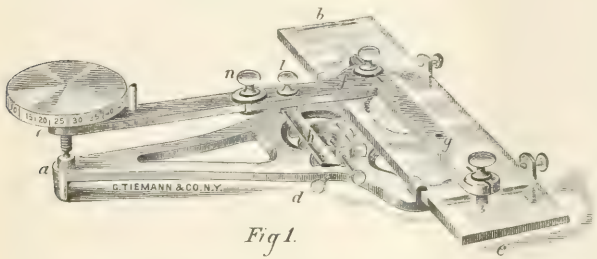

Fig 1.

An important practical question in connection with this instrument is whether the sections have parallel surfaces or are wedge shaped. The demonstration of the parallelism of the sections is as follows: Imagine a plane passing through the three points of the instrument, and call that plane the plane of the screw points. The edge of the knife is so situated that it is parallel to a line joining the upper two screw points (*f*, *g*, Fig. 1). Being a line parallel to a line in a plane, it is parallel to the plane itself, and therefore the edge of the knife is parallel to the plane of the screw points. It is immaterial in what position the micrometer screw is, for whether lowered or raised the edge of the knife is always parallel to the line joining the points of the screws on the short arm. If the sliding piece be placed upon the stand, the three points rest in the plane of the glass, because the bottom of the hole is in the plane of the glass; hence the plane of the screw points and the plane of the glass must coincide, and whatever is true of the plane of the screw points is true of the plane of the glass. Inasmuch as the edge of the knife is parallel to the plane of the screw points, it is parallel to the plane of the glass. In making the sliding motion along the glass plate, the edge of the knife remains at a constant distance from the plane of the glass; for its distance from the plane of the screw points is fixed by the micrometer screw. The edge of the knife, considered as a line moving over a plane to which it is parallel, and from which it remains a constant distance, must describe a plane parallel to the plane of the glass. Now, when the micrometer screw is turned so as to lower the long end of the sliding piece, and in that way lower the knife, the parallelism of the edge of the knife to the plane of the screw points is not altered, but the edge is nearer the plane of the screw points, and therefore nearer the plane of the glass than before. Having fixed the knife in this new position, the same conditions must be true as previously—that is, the edge of the knife must describe a second plane, parallel to the plane of the glass. As two planes parallel to a third plane are parallel to each other, the section which is included between these two planes must be bounded by parallel surfaces. True, the surface of the knife does not remain at the same angle to the plane of the glass; but as it is not the surface of the

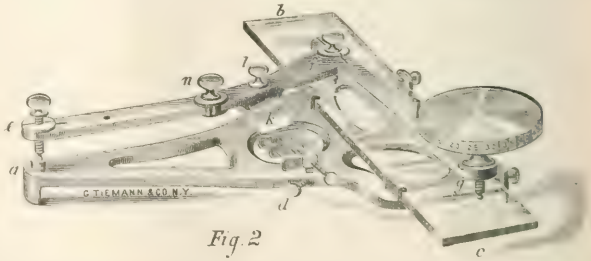

Fig. 2

[1] Read before the New York Pathological Society, February 10, 1897.

knife but the edge of the knife that determines the cutting, the difference in the angle between any two positions of the knife for a section of ten microns in thickness, which amounts to one-one-hundredth of a degree, should not make any difference in the cutting of a section. For specimens larger than one-half inch the position of the knife can be altered by a joint in the long bar, *n*.

For cutting paraffin the knife must be placed at right angles to the line of motion. For this purpose a smaller knife (*k*, Fig. 2), fitting into the same place as the larger one, is used, but with its edge standing in the other direction. As the two screws which are parallel to the edge of the knife must remain fixed, the micrometer screw and one of the other screws (*g*) must be made to change places. Owing to the principle upon which the instrument is constructed—*i.e.*, that the measurement is made at the end of the long bar, the knife being situated at the upper end—any possible error in the construction of the instrument will be divided by five at the knife. Mechanically it is just as easy—indeed, more easy—to construct a screw having ten threads to the inch as one having fifty threads to the inch.

The measurements are made as follows: The long arm of the sliding piece measures twelve and one-half inches; the knife is situated at a distance from the short bar equal to one-fifth of the entire length of the long bar; the screws have ten turns to the inch, so that a complete revolution of the micrometer screw lowers the long end of the sliding piece one-tenth of an inch. Inasmuch as the knife is situated at one-fifth of the distance from the point of rotation, the knife must be lowered one-fifth as much as the end of the long arm—in other words, for every complete rotation of the micrometer screw the knife must be lowered one-fiftieth of an inch. But there are one hundred divisions on the head of the micrometer screw; hence for every one of these divisions the knife is lowered one-five-thousandth of an inch, or five microns.

The theoretical advantages of the instrument are: (1) That inasmuch as the specimen remains absolutely fixed, the entire motion being limited to three points and one screw, the possible errors are diminished; and (2) that the errors in the knife are only one-fifth as great as any possible errors in the micrometer screw. It is important in this instrument, however, that the plane of the glass should coincide exactly with the bottom of the hole, and that the edge of the knife should be parallel to the plane of the screw points. The accuracy of the former can be easily determined by placing a ruler on the glass plate, and noticing where the ruler strikes the small projection at the apex of the stand. To determine whether or not the edge of the knife is parallel to the plane of the screw points, the ruler should be placed across the two screw points. On holding the ruler against the light, one obtains a reflex across the knife, and when the light is almost entirely cut off any lack of parallelism will be shown by an irregularity in the thickness of the band of light. If not parallel, the parts can be very easily readjusted.

The instrument is made by Tiemann & Co., of New York.

An Ephemeral Society.—A number of unmarried women in New York are reported to have formed a society for the prevention of hereditary diseases. They have registered a solemn vow not to marry any man whose family is tainted with consumption, insanity, alcoholism, or other heritable disease.

THE PERINEAL HORN—A NEW INSTRUMENT.

BY EDWIN DE BAUN, M.D.,

PASSAIC, N. J.

THIS instrument, which I have called the perineal horn, is intended to support the perineum during childbirth, and is to be used instead of the hand for bringing pressure to bear on the infant's head or presenting part and prevent the child from descending too suddenly, and also to assist in gradual dilatation of the perineal body.

Disadvantages of the Present Method.—(1) Pressure of the hand on the descending head or presenting part is rather difficult, as the surface is small, smooth, slippery, and therefore uncertain.

(2) Pressure on the perineum for any length of time produces more or less contusion with consequent

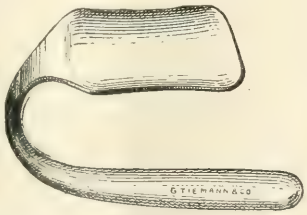

FIG. 1.

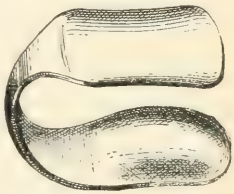

FIG. 2.

œdema, which renders the perineum very friable and therefore easily ruptured.

Advantages of and Directions for Using the Perineal Horn.—When the head impinges upon the perineum, place the concave surface of the horn against the infant's head or the presenting part, and between it and the perineum; then by grasping the handle or placing the ball of the thumb in the concavity of the handle (there are two instruments, the only difference being in the shape of the handles) you have by alternate relaxation and pressure full control of the case.

The presenting part should be allowed to descend during each pain as far as advisable, gradually distending the perineum, and finally, when the perineum is sufficiently dilated to meet the demands of the individual case, the presenting part may be pressed well up in the space beneath the arch of the symphysis pubis, thus applying the force or pressure not to the perineum but to the presenting part.

With the perineal horn the perineum may be supported by one hand, while with the other hand the forceps may, if necessary, be used with greater advantage than under the old method.

Should the perineum become partially ruptured, the extent of the lesion can be lessened by the use of this instrument.

I have used the perineal horn for about two years with very good results. The instrument is small, weighs only a few ounces, and can be conveniently carried in the pocket or obstetric case.

Messrs. George Tiemann & Co., of New York City, have very carefully carried out my ideas in making the instrument.

Serum Experiments. — Dr. Weisbecker (*Gazette Médicale de Liège*, June 24, 1897) has investigated the question as to whether the serum of convalescents has any action in an affection similar to that from which it was derived. To obtain his information he injected in two cases of typhus, five of pneumonia, and five of scarlatina serum from convalescents from the same diseases. He observed no modification, or local inflammation, or rise of temperature. Moreover, in all these cases the general state and the subjective state were ameliorated for some minutes after the injection.

Medical Items.

Contagious Diseases—Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, for the week ending August 7, 1897:

	Cases.	Deaths.
Tuberculosis	202	112
Typhoid fever	30	11
Scarlet fever	7	5
Cerebro-spinal meningitis	1	1
Measles	57	0
Diphtheria	150	22
Laryngeal diphtheria (croup)	4	0
Chicken-pox	4	0

Orrhodiagnosis.—The committee appointed by the chairman of the section on practice of medicine of the American Medical Association at the Philadelphia meeting made the following report: 1. In selecting the material used in making the test the choice between (*a*) serum, (*b*) dried blood, (*c*) fluid blood, and (*d*) blister fluid, will depend largely upon whether the object be scientific research, clinical diagnosis in hospital or private practice, or public laboratory diagnosis when the samples have to be sent some distance. 2. In spite of considerable variation in technique, there has been a remarkable uniformity in the results obtained by those taking part in the discussion, and their average of about ninety-five per cent. of successes agrees with the general average of the cases, nearly four thousand, thus far recorded in medical literature. 3. Each of several methods of technique advocated may thus give good results in the hands of those thoroughly familiar with the details found necessary in each case and the sources of error to be avoided, success depending rather on being perfectly familiar with one method than on the particular one selected. 4. For routine diagnostic work even the very simplest methods may give good practical results, but for recording scientific observations those methods which are accurately quantitative should be selected. This is especially necessary in reporting exceptional cases at variance with the general results recorded or when the observations are made the basis of generalizations. 5. A complete reaction should comprise both characteristic clumping and total arrest of motion occurring within a definite time limit. For practical diagnostic work a dilution of 1 to 10, with a fifteen-minute time limit, is convenient. In any doubtful case the dilution should be carried as far as 1 to 50, or perhaps 1 to 60, and a reaction not obtainable at that point should not be regarded as perfectly conclusive. For these higher dilutions the time limit should be extended to two hours. 6. Intensity of reaction in a given serum should be estimated by determining the degree to which it may be diluted without losing its power of giving a decided reaction, as both to agglutination and loss of motion. 7. The intensity of reaction shown by the same serum is influenced by the age, condition, and virulence of the test culture, and by the composition and reaction of the culture medium. For purposes of comparison the sensitiveness of the test culture should be taken into consideration. 8. The evidence so far recorded establishes that the reaction may be delayed or occasionally may not be obtained in cases of genuine typhoid infection; and also that it may be exceptionally present in non-typhoid cases, though not in an intense degree. 9. In investigating exceptional and contradictory results the following circumstances have to be considered: (*a*) The uncertainty of clinical diagnosis; (*b*) the absence of bacteriological or other confirmatory methods of diagnosis during life, giving decisive negative results; (*c*) the possibility of overlooking typhoid infection even post mortem, in the absence of characteristic intestinal lesions when a very thorough bacteriological examination has not been carried out. 10. The modifying influences mentioned above suffice to explain the divergencies existing in the reports of different observers. Without being absolutely infallible the typhoid reaction appears to afford as accurate diagnostic results as can be obtained by any of the bacteriological methods at our disposal for the diagnosis of other diseases. It must certainly be regarded as the most constant and reliable sign of typhoid fever, if not an absolute test. The committee stated, however, that this summary, while expressing the general consensus of opinion brought out during the discussion on serum diagnosis before the section on practice of medicine of the American Medical Association, did not claim to represent exactly the individual views of any one of those who took part.

Blood Stains.—The statement has been lately published that a warm solution of tartaric acid is most efficient in removing blood stains from towels, aprons, etc. Acetic acid has long been in use for this purpose, and either acid will probably answer equally well.

The Stabbing of a Fœtus.—The *Nursing Record* published recently a case of a woman who, when six months pregnant, was stabbed twice in the abdomen. Both wounds penetrated the abdominal cavity, and, as there were signs of internal hemorrhage, the abdomen was immediately opened. The uterus was found to have been perforated in two places by the knife. The hemorrhage was checked by stitching the wounds of the uterine wall. The patient progressed very well until the third day, when pains came on, and on the next day an abortion took place. The fœtus was dead, and examination showed that the knife had penetrated the left side of the chest, and had also wounded the small intestine in two places, purulent peritonitis having resulted. The case was regarded as especially noteworthy because of the peritonitis set up by an intestinal wound in a fœtus of that age, but it might have been caused equally by the introduction of septic matter from without on the point of the knife.

Health Reports.—The following statistics concerning small-pox, yellow fever, cholera, and plague have been received in the office of the supervising surgeon-general of the United States Marine Hospital service during the week ended August 7, 1897:

CASE EXAMINATION IN EPILEPSY.

BY L. PIERCE CLARK, M.D.,

FIRST ASSISTANT PHYSICIAN AT THE [illegible] SONYEA, N. Y.

THE desirability and necessity of having some systematic method of examining cases of epilepsy is but little recognized until one is called upon to examine many cases, either in private practice or in an institution especially devoted to the treatment of this disease. There are evidently many things which are necessary for the physician to know in regard to each particular case, aside from those included under the headings which are upon the symptom chart here submitted. For instance, it is desirable to inquire into the details of the alleged causes of the patient's epilepsy and all the possible or probable effects which any particular cause may have had upon the special case under examination. At the same time, when we have a chart upon which the principal general questions have been stated, we can very easily diverge at any point from the beaten path of routine examination.

The chart which is presented with this article was especially designed for purposes of examination of epileptics admitted to the Craig Colony. The manner in which this information is to be secured makes it easy to obtain it from the patient himself, or from the relative or friend who may accompany him. When considerable mental impairment has taken place in the patient's condition, it is almost impossible to obtain such information from the patient himself, even if he may be disposed to give it. In such cases admitted to the Craig Colony, this scheme for examination is supplemented by a blank form covering all unanswered questions, which is sent to relatives to be filled out. Obviously even all these efforts prove fruitless when the relatives and friends of the patient give vague answers to wrongly interpreted questions. The examination of epilepsy seems even more difficult to conduct than that of many other nervous diseases in which the mentality of the patient is materially at fault.

The writer desires to call attention to the necessity of making careful inquiry upon each particular heading in this chart, and he would also urge that a systematic and orderly manner of case taking is very essential in order to secure data of scientific value from a number of recorded cases.

Case Examination in Epilepsy.—Number. Name. Age. Religion. Social status. Address of nearest relative.

Family history (phthisis, rheumatism, inebriety, consanguinity, feeble-mindedness, rachitis, insanity, epilepsy, or other convulsive diseases). Number of brothers and sisters. Number of deaths in family and their cause. Habits of parents and relatives.

Personal history (prenatal causes if any, injury at birth, convulsions at birth, convulsions at dentition, diseases of childhood, scarlet fever, measles, typhoid fever).

Cause of epilepsy (syphilis, masturbation, sexual excesses, headaches, epistaxis, trauma).

Disorders of sleep in family or patient (night terrors). Paralysis in infancy.

Kind and quality of work while at school. Degree of education. Occupation and regularity of work.

First seizure. Character of disorder in consciousness. Aura. Subsequent stupor. Subsequent mental state. Subsequent paresis or aphasia. Character and duration of subsequent seizures. Time of day when attacks occur most frequently.

Manifestations of hysteria. Automatism. Hallucinations. Pallor. Flushing.

Primary movements. Order of invasion and side most affected. Sphincters. Conditions which cause or arrest attacks. Mental state in interim. Memory. Disposition. Frequency of attacks at present. Date of last attack.

Habits of patient (diet, appetite, digestion, sleep, alcohol, tobacco, narcotics).

Heart. Pulse. Circulation. Lungs. Respiration. Bodily condition. Hearing. Sight. Pupils. Speech. Skin. Bowels. Tongue. Superficial reflexes. Deep reflexes. Motion and co-ordination. Dynamometer: right, left. Stigmata of degeneration.

For women, menstruation (first occurrence, character, length of time present, regularity, relationship of seizures to menstruation or pregnancy, anomalies of menstruation at present if any).

In the beginning, as regards family history, although phthisis has been excluded by Gowers' as having no etiological significance in epilepsy, yet as epilepsy must primarily be regarded as a nervous disease of degeneration, we must take into account all hereditary characteristics which point to a degenerative condition of the family. Many German and French authors lay considerable stress upon phthisis as an hereditary factor in producing epilepsy.

Although the presence of neoplasms in family history has no direct etiological significance upon epilepsy, yet they, too, portray a certain element of family degeneracy in the organized tissues, which renders them an object of consideration in the study of the causes of any disease, especially in diseases which have such elusive and intangible dependencies as has epilepsy. The great influence of rheumatism and the gouty diathesis in the etiology of epilepsy has come to be recognized by most authorities. Although Gowers considers it of slight importance, rheumatism and gouty diathesis are diseases closely dependent upon disordered blood states, and especially upon abnormal metabolism, which, in turn, is closely associated with insufficient elimination of urea and its allied products. This latter principle has been carefully worked out by Haig, Bouchard, and others.

Inebriety: It has been estimated by competent authorities that nearly one-third of all epileptics have had intemperate progenitors, who were intemperate either before the birth of the patient or just at the time of conception.

Consanguinity has long since been recognized as an essential factor in considering family degeneracy. This condition is probably of more frequent occur-

[1] "Text-Book of Nervous Diseases," [illegible], p. 751.

rence in Europe than in America. In but one case has this factor been found to play an important part in examination of over two hundred cases admitted to the Craig Colony.

Gowers has stated that rachitis is a most potent factor in the production of epilepsy in infancy.

Epilepsy connected with dentition he would ascribe to rachitis primarily, the latter condition being based upon defective feeding. However true this may be in England, based upon this author's most extensive experience, the writer has not been able to elicit evidence to substantiate the fact that rachitis and defective feeding were the primary difficulty in epilepsy following convulsions at dentition.

Insanity again brings us to a point about which there are many mooted questions at present. It is questionable whether insanity predisposes any one to epilepsy, or gives even a basis for suggesting a hereditary characteristic which is transmissible in the form of epilepsy. When insanity is present in the family it certainly does predispose the individual epileptic to rapid and marked mental deterioration.

The significance of epilepsy in the family history should not be given so much importance as it has received in the past from the profession at large. The disease itself is not so certain of transmission, and, even if so, is not certain of direct transmission. Gowers states that the presence of epilepsy in an individual does not necessarily preclude his marriage, or if he does marry he is not certain to inflict the disease upon his immediate offspring. The author makes such careless statements in regard to this factor in producing epilepsy that the writer thinks it would bear much more consideration than he gives it.[1]

The presence or absence of other convulsive diseases, such as chorea, tic convulsif, habit spasm, occupation neurosis, etc., is desirable to ascertain, although too much emphasis should not be laid upon such information if they are found to exist.

The writer desires to call special attention to the scheme under personal history. It is extremely difficult to obtain valuable and accurate information bearing upon prenatal causes of the disease or any abnormalities existing at the labor period; for this reason alone, such information has relatively but little value. Convulsions at birth and at dentition should always be inquired into, as many persons are of the opinion that "spasms" at birth or at dentition are perfectly physiological and that they have no special significance in the child's growth or the after-development of the nervous system.

In about eighty per cent. of all cases of epilepsy admitted to the Craig Colony in which the convulsions began in early infancy they were found to be closely associated with dentition. Any abnormality of development in this epoch probably has more etiological significance than the mere process of dentition itself

In considering the infectious diseases of childhood, we would say that scarlet fever, measles, and typhoid fever represent, in the order named, the manner in which they have been the causation of epilepsy. Occasionally pertussis has been given as a cause, but in such cases it seems purely incidental. Measles is rarely found to cause epilepsy, while scarlet fever has been found in the examination of cases at the Craig Colony to be a more frequent and certain factor than have all the other infectious diseases combined. This statement is quite in accord with former statistics upon the subject.

Under the heading of causation of epilepsy, we would say that it is very difficult for one to elicit the proper information which has much or any bearing upon the real etiology of the disease. Whenever syphilis is present it is usually very easy to detect it, and seizures following syphilis of the brain are very easy of diagnosis by a careful observer. They should never be classed with true epilepsy, as they belong properly in that class known as epileptiform. Occasionally cases are seen following syphilis, in which the ravages of syphilis have been eradicated and yet convulsions continue; such resemble true idiopathic epilepsy, and have then probably become such to all intents and purposes.

Masturbation and sexual excesses have both been very much overestimated in the past, and are properly receiving at present but little attention as regards the causation of the disease, although when present such habits undoubtedly prolong and aggravate the malady.

The association which periodic attacks of headache and epistaxis have with disorders of the nervous system, as seen in epileptics, is very difficult of exact explanation, but that they do have some relationship to the disease is clearly proven in the case of six patients who were admitted to the Craig Colony, and in whom there was a record of periodic attacks of headache and epistaxis covering a period of four or five years prior to the occurrence of any seizure. Headache of this character must be differentiated from that following a slight petit-mal attack, which is frequently observed. Probably the conditions underlying both are analogous. Epistaxis frequently disappears as soon as the seizures become at all frequent. The exact explanation of the presence of both of these symptoms when they precede the development of true epilepsy it would be of great interest to ascertain by future study.

The disorders of sleep, night terrors, and nightmare, as found in the family and patient's history, are of considerable interest and give us some clew as to the sensibility of the cerebral cortex; or, in other words, they give us an idea of the manner in which the higher cerebral centres influence the motor areas, which points to the instability of the motor area of the brain in epilepsy. It is not an infrequent observation to see those epileptics who have had some disorder of sleep, either in their family history and in their own personal history, show themselves particularly liable to automatism following petit-mal attacks. It is hardly necessary for the writer to say that any paralysis from which the patient may have suffered in early infancy, if slight in character and transitory in duration, will manifest itself but little in later life. Infantile cerebral palsies are particularly difficult to detect. About eighty per cent. of all such cases become epileptics in later life. Only by close examination of the reflexes, dynamographic examination, and comparison of the extremities as to size, muscular rigidity, and tonus. can one detect the presence of a slight lesion of infantile paralysis.

The kind of education and the manner of obtaining the same are very necessary to a proper conception of the degree of mental force which the patient possessed in early life. The occupation and regularity of work which the patient has performed in the past also give one some idea of the capacity of the individual and the effects the epilepsy may have had upon the organism in causing it to depart from the normal social status of conduct.

Careful inquiry into the details of the first seizure shall be made before we can form a definite idea as to how severe the etiological factor may have been in the production of the patient's epilepsy. Quite frequently the alleged cause for the first attack is

[1] The writer deems this subject of so much importance that further comment seems necessary. In some twelve cases of epileptics admitted to the Craig Colony eight were married after their epilepsy had begun. Three were married after consultation with a physician, and in all cases a decided change for the worse was noticeable after marriage. Fortunately but few had offspring, and in most of these cases the children died in early infancy. In but one case have amicable relations been maintained between husband and wife.

only an excitant acting upon an inherited or acquired unstable organism. The kind, degree, and form of disorder in consciousness which occurred at the first seizure should be carefully studied. Just what change occurs in the material substratum underlying a disordered consciousness is still unknown; it is questionable whether this ever will be known, but in the mean time we should study all disordered states of consciousness, and ascertain as far as possible the influence which they have over the mental processes of the individual epileptic.

The great significance of the epileptic aura makes it a very important factor in the consideration of the epilepsy, as the aura generally indicates the part of the brain beginning the nervous discharge. It often is well marked at first, but dies out as the discharge gradually becomes more general or diffuse. The mental state subsequent to the paroxysm and presence or absence of aphasia or paresis following the seizure are all of great value in the study of the case. The manner in which all of the above-mentioned symptoms, connected with the first seizure, may undergo modifications in subsequent attacks should also be investigated, to aid in forming an opinion of the progress of the disease and what factors indicate a favorable or unfavorable prognosis.

There is a frequent association of hysteria in its many forms with epilepsy, especially in women and occasionally in men—which latter association, by the way, is much more frequent than is stated by text-books upon epilepsy. This heading in the scheme is a most important one for careful study, both at the primary examination and many times for months after. Many text-books state that the differential diagnosis between hysteria and epilepsy is very easy to make to one who is at all familiar with both diseases. The anomalous forms in which both diseases may be associated in the same case renders it practically impossible for the clinician to state that one disease is more pronounced than the other, which gives us the name of hystero-epilepsy.

The automatic state that usually follows petit-mal and psychic attacks, and occasionally after grand mal, is a desirable subject to investigate from the mental side of epilepsy. Frequently sane epileptics have hallucinations either of sight or hearing, without having any particular mental disturbances accompanying them. This fact has not always received as much attention as it merits. There seems to be no doubt that in many cases of epilepsy in which vivid hallucinations of sight and hearing were prominent, and also in which later in life epileptic seizures were common and frequent, these early hallucinations had some connection with the disturbed mental condition which finally culminated in the epilepsy. This statement well illustrates the place which epilepsy takes midway between a mental and true nervous disease.

The association which vasomotor disturbances have in connection with epilepsy has been a subject of considerable study, although but little definite information has been obtained concerning their interdependence. That pallor and flushing have some connection with the epileptic paroxysm is generally an acknowledged fact, although Gowers states that even though the face may be flushed it is no evidence that the brain is in a corresponding condition. Any one who has had personal experience with flushing and pallor of the normal state must be conscious of the close relationship between the vasomotor apparatus of the surface of the face and certain cerebral states, as illustrated by close study, intense application, or any kind of mental excitement.

Considerable attention should be devoted to the onset of the seizure, as to what muscles are first involved, and thus we will be able to reason *a posteriori* as to what portions of the motor cortex were first affected in the convulsive discharge. It is desirable that we should also know the muscles successively affected and the muscles which are most affected. For many reasons it is desirable that we should make careful inquiry as regards the action of the sphincters during the attack. Gowers states that these symptoms are produced in some other manner aside from the mental enfeeblement or loss of consciousness which is present in epilepsy, as some subjects always lose control of the sphincters in their attacks and others never lose control, although they may have epilepsy for years. Future study should enable us to clear up this matter, but at present it would be purely conjectural for us to formulate explanations for the presence of this disagreeable symptom. Some of the reasons put forward are that excessive muscular contraction forces the contents by a naturally unwilling sphincter; another is that the control of the higher cerebral centre is lost over the spinal-reflex centre; still another is given that the sphincters receive the initial shock of the cerebral discharge and are relaxed thereby.

Special attention should be given the examination bearing upon any particular excitant which causes an attack. Equal attention should be given to anything which arrests an attack, not only from a therapeutic standpoint, but because it enables us to know whether the patient has any hysterical symptoms attending the epilepsy. As the disorders of consciousness of epileptic seizures are almost invariably followed by a certain degree of mental impairment, we should know as much as possible about the mental state in the interim. Then, too, the memory in epilepsy is almost always impaired. This seems to be due, in a great measure, to the often reported disorders of consciousness.

We should know about the frequency of the early attacks and their frequency at present, in order that we may form a definite idea as to the prognosis and the kind and manner of medical treatment which should be given. The diet should be carefully inquired into from all points. Quite frequently after patient examination of a case, both through friends and the patient himself, one may elicit no information upon this point—when, almost by accident, the examiner will stumble upon some very important unhygienic condition which the patient and his friends thought was perfectly harmless. It is really the minutiæ of the daily life of the epileptic which give us a true insight into the malady and its treatment.

Appetite, digestion, sleep, use of alcoholics, tobacco, and other narcotics, are all obviously of great importance. The writer would warn any examiner from being led astray in obtaining information regarding disorders of digestion, as the epileptic is notoriously a hypochondriac.

In the physical examination it is unnecessary for me to emphasize the great importance of a careful study of the case from this point, as this not infrequently gives us a decided clew as to the true etiology of the disease. However the fact may be interpreted, it does seem that in the majority of epileptics heart diseases are much more frequent than many other organic lesions. The valvular lesion most frequently found is mitral regurgitation. One of the principal reasons for this condition is alleged by many writers to be due to an abnormal blood pressure, caused by the muscular contracture in the seizure.

Some writers have stated that the pupils of epileptics are unusually large and responsive to stimulation. Although the writer thinks that this statement will not be borne out by persistent and thorough examination in a great number of cases, yet some amount of attention should be paid to the pupillary reflexes in epilepsy, and these undergo various modifications before, at

the time of, and after seizures. It is doubtful whether there is much if any dependence to be placed upon the examination of the so-called deep reflexes, especially when they indicate a slight diminution. Not infrequently the condition of the reflexes of one side, as compared with the other, will show marked exaggeration. This should always be a sufficient indication for us to look for temporary exhaustion paralysis following the seizures; occasionally it is the one symptom present indicative of such a post-paroxysmal disorder. In almost all cases in which epilepsy has been existent for many years, a certain degree of disordered motion and co-ordination will be observed. Hughlings-Jackson has formulated a theory for this condition, in which he states that it is due to a gradual loss of memory impressions of motor acts in the brain, and that in each seizure there are lost successively less complex muscular movements which are never entirely regained. Notwithstanding that such a statement is very difficult of proof, it gains more credence the more carefully it is investigated.

Often an examination by dynamometer gives one the first clew to the presence of the effects of infantile paralysis, which, as mentioned before, is always very difficult to discover if the paralysis has occurred in very early life and the patient has been thereafter in strong and robust physical health. Again, it may give one a clew to a marked incapacity of one side of the body as compared with the other, without there being any cerebral or spinal disease underlying it. It may be a congenital defect, a real physical stigma of degeneration, closely allied to the well-known stigmata of asymmetries of the body.

In making a record of the stigmata of degeneration in epilepsy, we are forcibly reminded that this disease presents probably more stigmata of degeneration than all other nervous diseases combined. Sufficient explanation for this condition is still wanting. Slight errors of development which might be known as stigmata should not be given too serious attention, especially as regards the prognosis of the epilepsy. In the order of their most frequent occurrence, and probably in the order of their greatest significance, they are as follows: Palate, ear, asymmetry of cranium and face, general physical development. Although the presence of marked stigmata gives us some clew as to the probable deficient development of the cerebral centres, yet it should not influence us too much in declaring a particular case as without hope of recovery. Frequently in those cases in which stigmata of degeneration are most prominent, the least difficulty of ameliorating the severity of their epileptic seizures is noticed.

A word of warning should be given here against the possibility of mistaking stigmata of degeneration for the results of falls or injuries received by the epileptic, either before his seizures begin or after they are grand mal in character. Such injuries frequently resemble closely the various stigmata of degeneration found in the face and ears. In a measure this indicates why the deformity of the palate is most to be relied upon in making a just estimate of the influence the stigmata of degeneration have upon the patient.

Any abnormality found in the first menstruation (whether it be delayed or premature) is an essential factor in the examinations of female epileptics. It is essential to ascertain if any irregularity of menstruation is associated with the occurrence of a great number of epileptic seizures. The relationship which true epilepsy has to seizures which occasionally occur during the labor period is of considerable interest. Oftentimes a history of such association will be given to the physician by patient and friends when close observation will prove none to exist.

Although Gowers states that convulsions following the puerperal eclampsia rarely if ever lead to true epileptic seizures, at times it is very difficult to differentiate the convulsions of puerperal eclampsia from those of epileptic seizures which follow.

A CASE OF EUSTRONGYLUS GIGAS.

BY JOHN TRUMBULL, M.D.,

Concerning this large nematoid worm, which inhabits the pelvis of the kidney in certain carnivora and other mammals, Fagge says that it is "excessively rare in man." He, too, is authority for the statement that of the fourteen cases cited by Küchenmeister only four seem to be authentic, viz., those of Grotius in 1595, of Ruysch, of Blasius, and a more recent one of Moublet. The rarity of the disease is therefore sufficient warrant for immediate publication.

Being accosted on the street by a friend, who complained of a tightness across the chest, with pain which radiated down the right arm, and which, though coming on suddenly the night before with a sense of impending dissolution, had persisted till then, I insisted on having a specimen of his water, and promised to call round to examine his heart early the next morning. As the pain continued, he came to my office with a bottle of urine, and an appointment was made to see him in bed that evening.

The urine was clear and acid: specific gravity, 1.018; it gave a slight cloudiness in the upper half of the test tube when boiled after the addition of acetic acid.

My patient, Mr. E——, a former sea captain, seventy-three years of age, who has resided in Valparaiso for over twenty-two years in daily active employment, gave the following history: The night previous he had retired feeling perfectly well, but about midnight was awakened by severe pain across the lower portion of the chest, shooting down into the right arm. No shortness of breath, no pain on breathing, no palpitation or irregularity of heart action. The anguish disappeared, but the pain persisted. Questioning elicited the fact that for three or four years he has had to rise some four or five times during the night; and he has noticed that often, almost immediately after emptying the bladder, he feels impelled to rise again. The quantity of urine he admits to have been above the normal—"would half fill the vessel during the night." Now and then, after an attack of diarrhœa or cold, he remembers that the urine has been scanty and dark. He has never passed blood; never has had œdema of the feet, or puffiness of the lids, or morning headache; no pain in lumbar region; never conscious, he says, of having kidneys, lungs, liver, or heart. Three months ago, though regular in habit, he had a sudden desire one day to empty his bowel, and to his surprise passed about a quart of pure blood. Bleeding, though in much diminished quantity, recurred off and on for a month or six weeks. He had never suffered from piles.

Physical examination was purely negative, aside from a slight enlargement of the heart unaccompanied by increased arterial tension, and signs of arteriosclerosis.

While convinced that his attack had been one of angina pectoris, due probably to disease of the coronary arteries, I expected that the microscopic examination of the urine would confirm the existence of an interstitial nephritis. In going over a slide, twenty-four hours after the voiding of the urine, I had found three or four hyaline casts, when my attention was aroused by the appearance within the field of vision of a worm which was in active motion. It stretched clear across the field, and with slow motion curved anterior and

posterior extremities in opposite directions, until it assumed the outline of a figure-of-eight; when it slowly unfolded, to bend back again, or move the buccal end from side to side. It had the appearance of a diminutive angle-worm, tapering to a point at the posterior end; while at the head there was a much slighter narrowing, which ended in a circular opening. From this opening a fine thread-like process was seen to protrude now and then. Both ends were light in color, and of a faint bluish tint, though a dark line could be traced running from the mouth into the body. At the junction of the more transparent anterior portion with the more opaque portion of the body, which took place a little more than one-fifth of the distance toward the distal extremity, there were two dark spots which, in a couple of specimens found later on, had a very faint, distinctly pinkish tint. The rest of the body was of a dark, granular aspect, sharply defined, running the whole length of the worm to near the posterior end, and had on either side of the dark line which limited the granular portion a lighter transparent band between it and the cleanly cut outline of the worm.

I called my friend, Dr. Talavera, to see the worm: and from Rafael Blanchard's article on "Animal Parasites," in Salagar and Newman's "Examen Quimico y Bacteriológico de las Aquas Potables," was able to identify the worm as belonging to the nematoid group, and as being the strongylus gigas.

Valparaiso draws its main water supply from a river which flows bottom side up, so to speak, for the water is pumped from wells sunk in the Salto Valley, where there is an underground river except during the rainy season. The hill on which my patient resides has, however, for years been supplied with water from the Quebrada Verde—surface water. The possibility of a stray strongylus gigas having got in, from the water used to rinse out an empty medicine bottle, was present in my mind; but a second slide examined that evening dispelled such a supposition, for in it I found five worms, two of which were living, and nine or ten eggs. The eggs were ellipsoidal in shape, and sharpened at the poles; with small, scattered, bright points, surrounded by a dark border, which, while not so perfect as the illustrations of the ovum in Blanchard's article, yet hinted at the small openings in the fragile enveloping coat which allow of the nutrition of the developing worm by interchanges with the fluid in which it lies. The third slide gave me three worms and several ova; while in the fourth I counted thirteen worms of different sizes, and since then every slide has contained four or five.

As the patient passed the urine directly into the bottle, the large number of ova and growing worms found could scarcely have come from a few drops of water used for rinsing. On the other hand, the fact that these worms in macroscopic structure, so to speak, correspond perfectly with the strongylus gigas, which has its habitat in the pelvis of the kidney, makes it impossible for them to have come other than from the urine.

In the short article to which I have referred, the passage of ova only is mentioned, and not that of living worms. Here, however, we have a man advanced in years, with enlarged prostate, no doubt, who never succeeds in thoroughly emptying his bladder. In its albuminous fluid (is Bright's disease an essential factor in the development of this worm?) the ova receive ample nutrition, are kept at a uniform temperature, and hatch out. Thus it is that living specimens are voided, together with eggs more recently cast off by the inhabitant in the pelvis of the kidney. The hair-like process from the mouth, seen in the first living specimen, is doubtless the perforating tooth by which it makes its way through the intestinal wall to the blood-vessels, and thence is swept to the kidneys, where nutriment is to be found, indirectly, by going first through the veins to the heart. But for the fact that in the bladder there is an abundant supply of albuminous fluid ready at hand, there is no reason why the young worms might not pierce its mucous surface and thus themselves reach the kidney.

Since the above was written I have had two other samples of urine. With the first, which was only an ounce, eighteen or twenty slides failed to give me a single worm, though the sediment gave ample evidence as to the existence of a prolific breeder, it being lodged somewhere in the urinary tract. In the second specimen, just examined, I found several dead worms and pieces of worms (Fig. 1). In all of these the granules of the central portion were replaced by larger refracting masses, due to the products of decomposition, and with the slightest pressure of the cover glass these were expelled, so that the worm remained more translucent and homogeneous looking. Among the slides examined with this sediment I found the bodies shown in the accompanying illustration (Fig. 2). *A* was un-

Fig. 1.—Young Worms.

Fig. 2.—Ova and Débris of Shells.

doubtedly the vitellin membrane of an empty egg, whose pole had been ruptured for the escape of the embryo. It looked like a thin eggshell with the top cut off; and the upper lighter circle was clearly on a lower level, and formed, with the more sharply defined anterior edge, the rim of a cup-shaped hollow. The difference in thickness between the single integument in the circle and that of the rest of the mass, where the light came through two membranes, was clear and distinct. *B* was another ring of a perforated pole, with only a piece of the rest of the membrane attached. *C* and *D* are one and the same mass looked at in different positions as it tumbled about responsive to the impulse of expired air in breathing. These, and others figured in the lower right-hand corner, I take to be *débris* of broken-up eggshells.

The following gentlemen have seen my specimens, as I have been finding them, and have authorized me to cite them as to the genuineness of the case, and as to the accuracy of my representation of what was seen under a lens magnifying five hundred diameters: Dr. Olof Page, of the University of Pennsylvania; Dr. Luis Asta-Buruaga, of the College of Physicians and Surgeons, New York, and ex-interne of Roosevelt Hospital; Dr. Roberto Montt, of the University of Chile, who studied under Günther of Berlin and Levy of Strasbourg; Mr. Thomas Griffiths, associate of the Pharmaceutical Society of London. Dr. Luis Mourgues, of Paris, and Señor Cárlos E. Pórter, of the Municipal Laboratory, have already photographed one of the specimens under a high-power lens, but are waiting for a more favorable opportunity to secure better plates. They have been able to distinguish three small papillæ or nodules on the edge of the flattened mouth, and infer that the characteristic six will be found in a more perfect specimen. My representations of ova correspond with those shown in works belonging to the enthusiastic naturalist, Señor Cárlos E. Pórter.

The case merits study and a more detailed report, which will be forthcoming as soon as possible.

THE NERVOUS SYSTEM IN DISEASE.

BY JOSEPH F. EDWARDS, A.M., M.D.,

ATLANTIC CITY, N. J.,

FELLOW OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA; EX-MEMBER, STATE BOARD OF HEALTH OF PENNSYLVANIA; FOREIGN ASSOCIATE MEMBER, FRENCH SOCIETY OF HYGIENE, ETC.

SOME five years ago a girl of fourteen (a member of my own family), who had all through her life presented every appearance of robust health, after a period of close application to study commenced to present evidences of some little loss of her previously vigorous health; and one day said to me, laughingly: "I am getting paralyzed; I have no feeling in my fingers. You could cut them off and I would not feel it." For two weeks at intervals she would repeat this remark, then run off to her books or play, and no attention was given to these supposedly insignificant and meaningless complaints. It should be particularly noted that the outward, obvious evidences of departure from vigorous health were so insignificant as not to attract attention, and only to be remembered and recalled in the light of subsequent events. This young girl retired one night in her usual health. In the morning she was the sickest-looking child I have ever seen; she presented symptoms of perihepatitis, pleurisy, and subsequently double pneumonia, with death from heart failure at the end of two weeks.

In the very beginning of the illness I inquired into the condition of the different organs, to ascertain whether they would be likely to carry her through the contest. In the course of this examination, made at the onset of the disease, I was struck at finding in the urine an enormous deposit of the earthy and alkaline phosphates. Owing to personal reasons this case made a deep and lasting impression upon me, and this enormous phosphatic deposit was constantly in my mind, until, so to speak, unconsciously the question evolved itself, whether a broken-down nervous system had not preceded and made possible the development of the disease; whether we are not putting "the cart before the horse" when we teach that prostrated nervous systems are the results of disease; whether prostrated nervous systems are not always a necessary prerequisite of disease; whether that which we call the result is not, in truth, the cause.

Then I commenced to examine the urine of every patient that came before me, with the invariable result of finding a very great deposit of phosphates in all conditions of weakness or prostration, and an extremely slight deposit in disorders not attended by prostration. Then I began adding to my routine treatment for the particular disease under consideration nerve tonics or nerve sedatives, as I would find an excess or deficiency of phosphatic deposit. My results were good; so very good that I found myself securing the reputation of a "specialist in nervous diseases" among my patients.

Then I commenced to look for a theory that would fit into my observation and experience, and I elaborated the following doctrine, a brief outline of which I now submit to my professional brethren.

I have come to regard the various organs and parts of the body merely as agencies for the manifestation of a force that is generated in the nervous system. The functions of digestion, assimilation, excretion, circulation, calorification, respiration, and so on throughout the whole list of vital functions, I have come to regard as manifestations of a force generated in the nervous system. Just as one central dynamo may furnish heat, light, motion, or sound, in accordance with the construction of the agency through which the force generated in and by the dynamo is made manifest—so the stomach will digest, the kidneys will excrete, etc., not because of any power resident within or generated within themselves, but because of a latent resident power incited to activity by the force generated in the nervous system. In other words, my idea is that, while capable of function, no organ can originate within itself the force necessary for its function. The carbon points are necessary for the manifestation of the electric light; the car is necessary for the manifestation of the electric force generated for motor purposes; but neither the carbon points nor the car are capable of generating this force within themselves. The stomach, liver, spleen, kidneys, lungs, heart, etc., are all necessary for the manifestation of vital force familiar to us as life, but not one of these organs can originate within itself this force.

According to this doctrine, we would be compelled logically to regard the nervous system as the vivifying, regulating, controlling portion of the body, and so I took it to be; I did not, and do not, think that I am advancing any new physiological doctrines, but simply that I am suggesting a wider and more universal application of those already taught. So I thought, until I was staggered by the replies received by me from the professor of physiology in one of our leading medical colleges, to some queries bearing upon this question.

1. Is not the nervous system the only portion of the body capable of originating force? To this query our professor replies, No.

2. Can any organ perform its function because of a force or power originated within itself, independently of the nervous system? To this query he replies, Yes.

3. Would functional activity be possible without the force originating in and transmitted from the nervous system? To this he replies, Yes.

Now, while these replies may be in accord with physiological teaching, are they correct?

The affirmative reply to query No. 2 would seem to imply that each individual organ of the body constitutes in itself an entity capable of independent existence. Is this correct?

Does not an affirmative reply to query No. 3 imply that the voluntary muscles possess in themselves the power of contraction and relaxation independently of the nervous system, and, if this be true, why does paralysis of certain muscles follow a remote injury that interferes with the transmission of force from the ner-

vous system to these muscles? If the bladder can perform its function independently of the nervous system, why does paralysis thereof result from injury to the cord? If the heart is a complete entity, capable of independent function, why will destruction of the cerebellum arrest its action?

These queries have arisen in connection with my doctrine that a disordered nervous system is a prerequisite to the existence of disease.

It seems to me that we can make two grand divisions of all diseased or disordered conditions:

1. Functional derangements, in which there is no alteration of structure; simply a defect in quality or quantity of vital force.

2. Nutritional or organic, for in all organic diseases not mechanical the fundamental lesion is an alteration in the structure of the diseased part; hence it is a nutritional change.

If, then, the nervous system originates the force or power necessary for function; if nutrition is a function; if a normal nervous system will originate normal, and an abnormal nervous system abnormal force —does it not logically follow that an abnormal nervous system must precede an abnormal functional or nutritional derangement of any organ or part, that is not mechanical or produced by a mechanically acting cause? Let it be understood that when I speak of the "nervous system," I am not confining my reference to the brain and spinal cord, but that I include, of course, nerve tissue wherever it may be found. With this understanding, is it not true that the nervous system is the only portion of the body capable of originating force; that a normal nervous system is absolutely inimical to an abnormal condition of any remote organ; and that, in seeking to locate the seat of original departure from health, must we not look for it in some abnormal condition of the nervous system? If my contentions are correct, will it not logically follow that, with organic disease in which some organ is so damaged structurally as to be incapable of perfect function, the measure of function to be derived therefrom will depend upon the quantity and quality of vital or nervous force with which it is supplied, and that the quantity and quality of this force will depend upon the degree of integrity of the nervous system that originates it? Hence are we not compelled to fall back upon the nervous system as the ultimate element in etiology, and to start with it as the primal element in therapeutics?

A PLEA FOR THE MORE GENERAL USE OF THE ENDOSCOPE IN CHRONIC URETHRITIS.

BY ALBERT A. BERG, M.D.

NEW YORK.

THERE is probably no one affection of the many that present themselves daily to the general practitioner that deserves more careful consideration or demands more serious thought on his part than does the treatment of chronic urethritis, yet, in spite of the great frequency of this condition and its obstinacy in yielding to the usual methods of treatment, the general practitioner still clings to the long obsolete measures of internal medication or injections of one of the too numerous astringent solutions. The success of this plan of treatment we know only too well, for the numerous cases of gleet and stricture that are constantly presenting themselves to the specialist are only too forcible reminders of its inefficacy.

A short *résumé* of the local conditions found in most cases of chronic gonorrhœal urethritis will at once make clear the reason for the failure of these therapeutic methods.

Lesions of Chronic Urethritis.—An acute gonorrhœal urethritis follows one of two types: (*a*) Either it is a mild inflammation with simply a swelling of the mucous membrane and desquamation of the superficial epithelial cells; or (*b*) A more severe inflammatory process with erosion and ulceration of the mucous membrane in addition.

It is quite evident that the first class of cases, which fortunately is the more frequent, will tend to heal spontaneously. The inflammation subsides in about ten days, there is a complete regeneration of the epithelium, and the urethral canal returns to its normal state.

It is hardly necessary to do anything for this class of patients beyond relieving the burning on urination, restricting their diet and drink, and keeping their urine slightly acid. Injections, if used at all, serve only to remove the products of exudation and inflammation from the urethral canal; hence they should be as mild as it is possible to have them.

In the more severe cases the lesions produced by the inflammatory process render a complete regeneration of epithelium an impossibility, because the epithelial layer of the canal at the site of these ulcerations has been destroyed. When the ulceration heals, it does so by the process of granulation, and so the epithelium is replaced by connective-tissue cells and stroma. This can easily be demonstrated by viewing a urethral mucous membrane which is the seat of such an inflammatory process, several days after its onset, by means of the electro-endoscope. We find the mucous membrane swollen and congested, and in isolated spots ulcerated and eroded. Viewed at a little later stage, the site of these ulcerations is seen to be covered by granulations which appear as small, rounded, reddened masses. Microscopical examination of such a granulating area shows it to be made up of round cells and numerous blood-vessels; the surrounding tissue is thickened and infiltrated with similar cells, and the surrounding epithelium has changed to the pavement variety. This pathological condition of the mucous membrane of the urethra has been termed granular urethritis.

Now let us see what the results of such granulating areas in the urethra are. (*a*) When the granulations become exuberant they more or less completely block up the urethral canal, lead to stagnation of urine behind the obstruction, and so produce secondary changes in the otherwise healthy mucous membrane. (*b*) The longer these granulations persist, the larger they will become, and the more marked will the infiltration of the surrounding tissues be, for the constant passage of urine over these raw surfaces tends to irritate them and so stimulate the growth of granulations. (*c*) The result of this infiltration is a thickening of the mucous membrane and consequent narrowing of the canal.

These three factors lay the foundation of all the cases of chronic gleet and stricture, results that could possibly have been avoided if the existing conditions had been met in the right way from the very onset of the trouble.

Bumstead in his "Venereal Diseases,"[1] says: "Besides the discharge which comes from the presence of granulation tissue the narrowing of the canal, due to the thickening of the mucous membrane, has been demonstrated as capable of causing an indefinite continuance of a urethral discharge."

Therapeutics.—It becomes then a matter of considerable importance to be able to recognize and treat these granulating areas at as early a stage as is possible. Then when are we to commence the treatment;

[1] Page 341.

and how are we to treat these granulations in the proper and rational method?

It is well known that during the first or acute stage of an inflammation the less the active treatment the better for the inflammation, because the process which has been inaugurated cannot be aborted, and because any irritation of the inflamed part increases the severity of the process. Hence during the first ten days of any acute urethral inflammation we follow merely the symptomatic method of treatment. If the process is a mild one it tends to heal spontaneously and needs no interference on our part. If the process is a more severe one we wait until the acute stage has subsided, which is about the tenth day, and then proceed to aid in the healing of the ulcerations, which are the cause of the chronicity of the discharge and the subsequent malconditions in the urethra.

In considering the therapeutic measures to be applied to the conditions as outlined above, we will be most successful if we follow those lines of procedure which have proven most beneficial in similar conditions on the external surface of the body. When we deal with granulating areas here, we direct our efforts (1) to protecting the granulations from irritation: and (2) to preventing these granulations from becoming exuberant, for this interferes with their healing.

Both of these conditions are met by the use of nitrate of silver, for this produces when applied to a granulating area a protective film of the albuminate of silver, beneath which healing may occur, and, secondly, prevents the granulations from becoming exuberant. Moreover, and very important in the consideration of lesions in the urethral canal, the silver nitrate tends to soften the infiltrated area, and so favor its removal by absorption. This then would appear to be the ideal method of treatment of a granulating area, and the question now arises: How should we apply the silver? Two methods are available: (1) Flushing the urethra with solutions of silver nitrate; (2) Direct local application of silver nitrate to the granulating spots.

Let us consider the advantages and disadvantages of these two methods. In favor of the former we can only say that it requires very little knowledge to carry it out, and is easily and quickly done. But it has many disadvantages:

(*a*) It is hardly to be expected that we can reach deep-seated lesions by an anterior injection, and if deep injections are made there is the danger of forcing the fluid down through the seminal ducts into the epididymides and testes.

(*b*) The healthy urethra is, moreover, subjected to the same treatment as the diseased areas, and it is to be expected that from the constant irritation of these caustic solutions it soon takes on a reactive inflammation.

In favor of direct local application we can say that we deal directly and solely with the diseased areas. There is no danger of epididymitis or orchitis, and with a few trials the application becomes just as easy as irrigation.

Direct local treatment of the urethra is made possible by the use of the endoscope. With the aid of the Otis electric-light attachment, a complete view of the urethral canal is afforded. A positive diagnosis of urethral affections can thus easily be made, and treatment easily carried out.

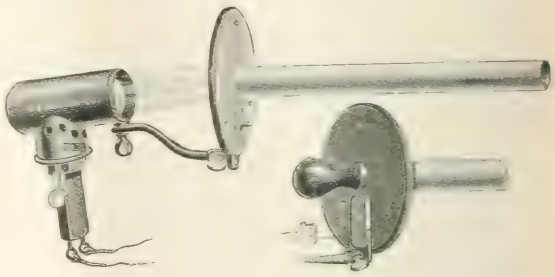
The requisites for such examination and treatment are: (1) A set of short and long endoscopic tubes: (2) a constant battery; (3) an Otis electric attachment.

1. The endoscopic tubes are made in two lengths, depending on whether they are to be used in the anterior or deeper urethra. They vary in calibre, a set of three being sufficient—10 F., 20 F., and 25 F.

They are usually made of coin silver, but may be made of hard rubber. If made of silver, it is best to have their interiors blackened so that the shining surface of the silver may not interfere by its reflection of the light.

2. The battery should be a constant one. One or two Daniell cells are sufficient. It should be strong enough to supply the lamp in the electric attachment, without consuming the film too rapidly.

3. The light: The best form of illumination is the electric light, which can be attached to the endoscopic tube, as shown in the sketch. The Otis light is a very good form. After a little practice the sun's light reflected into the tube by means of a head mirror will serve the purpose very well. The technique of the procedure is as follows:



The patient is placed upon his back. The urethra is first thoroughly cleansed by irrigating it with hot saline solution or a mild antiseptic solution, *e.g.*, corrosive sublimate 1–10,000. The endoscopic tube with its obturator, the latter serving only to facilitate the introduction of the tube, is introduced to its full length, and the obturator withdrawn. As large a tube as the urethra can comfortably accommodate is selected. The light is now thrown into the tube and a systematic examination of the mucous membrane is made, the endoscope being slowly withdrawn so as to bring the entire mucous membrane successively into view. Each ulceration is noted and located. Having thus made an accurate diagnosis of the condition of the urethra, we are ready to proceed to its treatment. The endoscope is again introduced, the obturator withdrawn, and the deepest granulation (for it is best to commence with the deepest lesions) is brought into view. An ordinary applicator, carrying a piece of absorbent cotton firmly wrapped around its end, is dipped into a twenty-per-cent. solution of silver nitrate, and introduced through the tube, touching the granulating area. Two or three such spots are treated at any one sitting. The patient is to lie quiet for fifteen or twenty minutes after such treatment, for the smarting is at times considerable. He is also to be told that the discharge will increase on the day following, but will then subside. Such applications are to be made twice a week, and in the interim the patient washes out the urethra with a mild solution, so as to keep the canal clear of pus and detritus. Each granulating spot is treated in this manner, and generally in about three weeks a complete healing has taken place.

It is to be borne in mind, however, that if a stricture has formed in the urethra the presence of this alone is sufficient to keep up a gleety discharge: hence the subsequent treatment of the stricture by dilatation

is important if a gleety discharge persists after the mucous membrane has entirely healed.

What is especially to be remarked about the direct local treatment of ulcerations in the urethra is that the healing when brought about is of a permanent character, not to be compared to the healing which has occurred in so many patients discharged as cured, but who after a slight excess *in venere et Baccho* have a return of their old trouble.

I have selected this one pathological state of the urethra for treatment by use of the endoscope merely because it is the most common, but the use of the endoscope in the urethra is by no means limited to this field. A wider and more systematic use of the endoscope in all urethral affections, from the simplest to the most complicated lesions, will lead us on the one hand to a more accurate diagnosis, and on the other to a more rational method of treatment.

A few cases will serve to illustrate the advantage of direct local treatment in urethral affections.

Case I.—E. A——, aged nineteen years, had several attacks of gonorrhœal urethritis. The attack from which he was still suffering commenced about eight months ago. He went through the regular course of internal medication and injections, but the discharge continued. About this time his physician injected into his urethra a twenty-per-cent. solution of nitrate of silver, with the effect of increasing the discharge and causing the patient considerable pain. When he came under my treatment he had in the scroto-penile urethra four granulating areas. He was at once subjected to direct local treatment with silver, and advised to flush the urethra three times a day with one per cent. of sulphocarbolate of zinc. In three weeks the granulations had entirely healed, but the presence of a stricture kept up a slight discharge, which disappeared as the stricture was dilated.

Case II.—M. T——, aged nineteen years, had one previous attack of gonorrhœa. The present attack was of two weeks' standing. The discharge was gleety, and there were some pains and tenderness in the anterior urethra. Examination with the endoscope revealed the presence of several granulation areas in the anterior urethra, and at one point considerable perifolliculitis. The granulations and folliculitis were subjected to the direct local use of silver, and rapid healing with complete cure resulted.

Case III.—A. S——, aged twenty-four years, had several previous attacks of gonorrhœa, this last attack of several weeks' duration. He had used injections faithfully, but his discharge continued. Endoscopic examination showed the presence of several granulating areas in the penile urethra. These healed rapidly under local applications of silver, with a complete cessation of the discharge.

[redacted]

Pes Cavus.—The treatment consists in division of the plantar fascia, after which extension should not be made for three or four weeks, as cicatricial thickening and pain are thereby avoided. The best apparatus for after-use is a tin shoe with a divided sole plate, so arranged that the front part of the foot may be uplifted and brought into the same horizontal plane as the heel. The raising of the front part should be done gradually, as some pain incidental to the rapid method is thereby avoided. If there remain much rigidity of the tissues afterward, a second operation is advisable; or considerable relaxation of the fascia may be obtained by soaking the foot in hot water containing bicarbonate of sodium, afterward manipulating it freely and stretching the sole. The relief afforded by this simple operation of section of the plantar fascia is very considerable indeed.—Dr. Tubby, *The Clinical Journal*, April 28th.

MEDICAL SELECTION FOR LIFE INSURANCE.[1]

By Brandreth Symonds, A.M., M.D.,

[redacted]

It has often been stated that no selection is necessary for life insurance, and the argument is something like this: All men have to die. Why not therefore calculate upon the mortality of the whole population and admit them all to life insurance? Some expense, that of medical investigation and some others, are thereby saved and at the same time the opportunity is given to everybody to partake of the blessings of insurance. Something of this kind is now under trial in Germany. It is a stupendous scheme of insurance against invalidity and old age but does not contemplate life insurance. Nearly all wage earners over sixteen, whose average annual earnings do not exceed about $500, are compelled to participate. A most elaborate system of registration and espionage has been devised, so that no person of the twelve millions or more entitled to its benefits may escape the blessings thus thrust upon him. This plan has not yet been tried long enough to determine its stability; but we could draw no inference even from its success. It is a scheme forced by an almost autocratic government upon a submissive people, at least more submissive than we are. How would it succeed if applied to our life-insurance methods? A life-insurance association or company of today is, with us, a voluntary aggregation of individuals. If there were no way by which those who are below the present standard of prospective longevity could be excluded from its advantages, it would be composed exclusively of such inferior specimens. Consequently the mortality rate would be vastly higher than that of the average population. No sound person would join who could obtain insurance in a company that adopted a higher standard. Man is indeed becoming more altruistic, and the growth of life insurance itself would indicate this. But his altruism is yet far below the level which would cause him to make personal sacrifice of strength, time, and money for the benefit of some unknown stranger, perhaps thousands of miles away. He is eager to make such an offering upon the altar of his home, when he can thereby save his wife and children from want, perhaps shame and dishonor. But he would make no such effort for the unknown weaklings who as a class will surely die before their time. He wants to associate himself with those who are as strong as he is, and whose expectation of life is as great. Therefore the interests of the policy holders who are already in a company demand that none be admitted unless they be up to the standard already adopted. On this account the best medical skill is employed to watch that the maimed and halt are kept out.

Selection of risks for life insurance is not necessarily medical. For example, in some associations only total abstainers are admitted, and this precedent must be regarded as a form of selection. Again it is found that those risks who take the higher-priced policies compare more favorably with the average than those who take the cheaper ones. This form of natural selection is of decided consequence to the company, but is in no sense medical.

The points which enter into the medical judgment of a risk may be grouped under four heads: (*a*) Present physical condition: (*b*) Previous personal history as regards disease, habits, etc.: (*c*) Family record as regards disease and longevity: (*d*) Material environment, including occupation, climate, etc.

(*a*) Comparatively few of us are in a perfect phys-

[redacted]

ical condition, and in many cases much judgment is exercised in determining what variation from the norm is sufficient to disqualify an applicant. Any abnormality which causes a shortened class longevity among those who are afflicted with it must be regarded as a sufficient disqualification. In some cases temporary ailments should cause a postponement until the restoration to health. It is hardly proper to pass any acute disease as trivial. An attack of apparently acute bronchitis may be the forerunner of some serious mischief in the lungs; a simple diarrhœa may be the premonition of typhoid fever. On the other hand some chronic abnormalities, though pathological, do not warrant us in excluding a case. Such a condition as a few bilateral pleuritic adhesions at the base of the lungs, if it can be determined that they are old, ought not singly to be a cause for rejection. But chronic pulmonary or pleuritic conditions are rarely presented to a life-insurance examiner, simply because most people know that such diseases are almost invariably bars to insurance.

Not infrequently a person has no idea that he has any trouble with his heart until he is rejected by some insurance examiner. It may seem hard at times to refuse some of these cases, the damage is so slight and the compensation is so perfect; but all organic lesions of the heart ought to be rigidly excluded. It is fortunately true that some of them live for many years and finally die of intercurrent disease, but unfortunately we can rarely pick these cases out of the mass. The same rule applies to some of the so-called functional diseases of the heart, such as angina pectoris, and that symptom complex known as exophthalmic goitre, in which the frequent heart action is a marked feature, although the disease is not often regarded as essentially one of the thyroid gland. On the other hand a mild acceleration of the pulse is usually found in those who are being examined. I have frequently found a pulse rate of eighty or more in my examinations. Now that is above the average even in these days of hurly-burly and must be regarded as the evidence of slight nervousness of which the applicant is unconscious, or at least says he is. Recognizing this, we do not hesitate to accept pulse rates up to ninety. When it remains persistently above this point, it becomes a factor of more consequence, as it may be the only evidence we have of beginning renal, pulmonary, or nervous disease. Or it may indicate a diminished vitality, impaired by overwork, dissipation, etc., not in itself alarming, but a serious complication of any acute disease which might happen along. But there are a few cases in which the acceleration of the pulse has lasted over many years of continuous good health, and these may be regarded as cases of personal idiosyncrasy and not necessarily unfit for insurance. The evidence, however, must be very convincing. Similar considerations influence the disposal of cases of other alterations of the pulse rhythm, such as too infrequent a pulse and intermittent or irregular pulses. As long as these conditions are present they are bars to insurance usually, and the exceptions to this rule must be very rare.

Comparatively few suspect any pathological condition of the urine until examination reveals it. They feel in good health, are vigorous and active, and they resent, as a personal insult in some cases, the statement that the condition of the urine revealed by the examination is unsatisfactory, and that they cannot obtain insurance on account of it. I know of nothing more trying to the tact, temper, and patience of the medical examiner than the endeavor to smooth some of these ruffled dignities. I have had men who knew better tell me that they ought to be accepted for insurance because, forsooth, they felt themselves to be perfectly well, and knew that they did not have any disease, although they had been told that the urine contained albumin or sugar. If such were the standard for life insurance, our duties would be very much simplified.

Let us consider this topic more in detail. I am convinced that the presence of genuine albumin in the urine is always pathological.[1] It may be due to pus or blood, the sources of which may be various, but in the great majority of cases the albumin is of renal origin. In these cases it may be temporary or permanent. If permanent, it is due to some organic change in the kidneys, which may or may not be progressive. If temporary, it is due to some inflammatory or degenerative or vascular disturbance of the kidney, which sooner or later passes away entirely, leaving no trace behind. In many of these cases the individuals are below par generally while the albuminuria lasts. In some, dietetic errors, muscular exercise, and other causes play a part. Some are convalescing from a febrile disturbance, such as a cold or a diarrhœa. During the epidemics of influenza albuminuria is very often found among those who have this disease even mildly. A favorite time for its occurrence is between the ages of fifteen and twenty-five. In a fair proportion of cases no cause whatever can be assigned. But, whatever the cause, the presence of genuine serum albumin in the urine must be a bar to insurance until it has completely and permanently passed away. I say genuine serum albumin, for undoubtedly many mistakes have arisen from confounding other substances, notably nucleo-albumin, with this. Investigators in this line have endeavored to seek out delicate tests at the cost of accuracy. Many of these tests respond to the presence of even very small amounts of serum albumin, but unfortunately they react well with some other substances, notably nucleo-albumin. This statement applies certainly to all tests in which organic acids, particularly acetic acid, are used. I feel therefore, that injustice has been done heretofore to a large class of applicants whose urine on more particular examination would now be regarded as healthy.

Similar considerations confront us when we detect the presence of sugar in the urine. Nearly all the tests for sugar are simply reduction tests, upon which other reducing substances besides sugar may act. Some reducing substances, such as creatinin, are always present in the urine, but normally in too small quantities to give a reaction. Many drugs, such as rhubarb and chloral, when excreted, act as reducing agents. At times some abnormal ingredients, such as glycosuric acid, cause the same difficulty. Now merely because the urine happens to be concentrated and the creatinin, etc., are in sufficient quantities to have a reducing power, or because the man ate a big dinner and took a rhubarb pill after it, or because he had headache and took a does of chloral the night before examination, and as the result of any or all of these our ordinary sugar tests show a reaction, it is certainly not right to refuse that man insurance on account of glycosuria. The usual tests are prompt, convenient, and sufficiently delicate, and are therefore all that we need for negative results. But if we obtain a positive reaction, we should in all cases seek to confirm it by a further accurate test, such as the phenylhydrazin test or the fermentation test.

Of course permanent glycosuria acts as a bar to insurance, but what importance shall we attach to transient glycosuria? This term should be applied to cases in which the absence of sugar is not brought about by changes in the diet, for we all know that in some cases of diabetes the sugar can be made to disappear entirely for some time from the urine simply by the thorough elimination of starches and sugars

from the dietary. No one, however, regards such an aglycosuria as healthy, and when sugar is found every time that a man relaxes from a rigid diet the case must be deemed from a life-insurance point of view as hopeless as if the glycosuria were permanent. But real cases of transient glycosuria do occur, though they are much rarer than those of transient albuminuria. These persons are more often quite stout, sometimes very fat, and their obesity is apt to run to large and pendulous abdomens. It is possible that the dragging on the liver by the falling abdominal wall, with the consequent disturbance of the hepatic circulation, may act to produce glycosuria, for in some cases this is entirely removed by the use of a snug supporting abdominal belt. Most of these cases are non-insurable on other grounds than the presence of glycosuria, but occasionally that is the only bar. In such cases, when the sugar has disappeared from the urine, it must be determined by repeated examinations that it stays away and that this absence is not due to any change in the diet. We should also seek for some cause for the temporary glycosuria, such as the ingestion of sweet wine, of candy, or of fruit in excess. Nearly all these cases should be postponed for some months, but ultimately after careful investigation a few may be accepted.

(*b*) When an applicant states that he has had any sickness, the questions that arise are: Has it left any permanent disability? Has it a tendency to recur? Is it the symptom of a serious disease?

A permanent disability would usually be found on examination, but not infrequently our methods of physical exploration will fail to reveal the latent sequel of a disease, especially if it involves the abdominal or pelvic organs. There may also be some doubt in regard to the technical skill of our examination. For these reasons a risk is usually postponed after a severe illness until such time as would make the latent sequels manifest if there were any such.

Some diseases have a tendency to recurrence, and this must be guarded against by postponing consideration of the risk until reasonable danger from this cause has passed. Each of such diseases must be considered separately, for the same rule will not apply equally to gout and appendicitis, to rheumatism and gall stones. In cases in which the disease has recurred repeatedly, insurance should be withheld either permanently or until many years after the last attack.

Certain conditions, inconsequential in themselves, are of importance as being the manifest symptoms of deeper and more serious trouble. The loss of two or three drachms of blood is a matter of no consequence, *per se*, but if it comes from the lungs it is of the greatest significance and must be regarded as very serious. In Dr. Marsh's report on the mortuary statistics of the Mutual Life Insurance Company of New York, he says: "The general ratio of the consumption mortality was 19.74 per cent., while in these cases [those in which a history of hæmoptysis was given] it is 34.92 per cent., or nearly double. . . . In less than half the cases the supposed source or cause of the hemorrhage is given, and in the majority of these it was reported as slight, as coming from the throat and nose, or as the result of an injury or excessive exertion. These explanations are mostly given in the consumptive cases, and our experience shows that statements indicating the cause of the hemorrhage are usually untrustworthy, as patients always, and physicians sometimes, are apt to delude themselves with the most hopeful views."

(*c*) When we come to look at the family history of an applicant, we are confronted with a great difficulty, the lack of accurate knowledge on many points that are essential. For instance, very few can give the full names of all their four grandparents. Ignorance on a point considered by most people so essential as this indicates even greater lack of knowledge about the duration of their lives and the cause of their deaths. We have to pierce through this haze of misinformation and imperfect knowledge as best we can. Fortunately, as a rule, the applicant for life insurance gives the most favorable presentation that he knows or does not know. He not infrequently states that his parents died of "natural causes," or still better, of "nothing serious." Of course he means to imply that the cause of death was not one of those diseases which are usually regarded as hereditary. It follows naturally that we put the worst possible interpretation on all equivocal answers in the family history. This feeling of distrust is justified by certain facts. Thus Manley investigated certain cases in which there was a family history of consumption.[1] To offset this family history policies were issued only when such applicants were physically above the standard. In spite of this superior physique, the mortality proved to be above the average. Where only the father was consumptive, the actual mortality was twenty-four per cent. in excess of the expected; where only the mother was consumptive, the actual mortality was twenty-five per cent. in excess. But now note this: where the father did not die of consumption and the mother's death was ascribed to childbirth, the actual mortality was twenty-eight per cent. in excess of the expected. In other words the death of the mother from childbirth had as unfavorable an influence upon the longevity of her offspring as her death from consumption. The most plausible and the most probable explanation of this is that these applicants made a mistake when they stated the cause of the mother's death. The idea of consumption is so dreaded, by the laity especially, that a case of it in the family is forgotten as soon as possible, or some fable about it is gradually invented, amplified, and polished, until finally it passes as the truth.

On the other hand, we tend to give less and less credit to hereditary influences in the development of certain diseases. Tuberculosis is now recognized to be a germ disease and distinctly contagious. If the dose of the tuberculous poison is sufficiently large, any man will die from it, no matter how great his strength and vitality. If the husband develops consumption, and the wife, in her tender, loving care, becomes infected by him and both die of it, surely it is not right to credit the children of these with a double inheritance of this disease. The inability to resist such a destructive process is almost the only part that is inherited, and this can largely be determined by itself from the physical examination and the previous personal history of the individual. Necessarily much precaution must be taken in selecting such cases, and only those which are distinctly above the average in both these respects should be admitted to life insurance on terms of equality with others. The possibility of any present family contagion should be carefully guarded against. A person who is living with a tuberculous relative is in much greater danger than one who has lost several relations eight or ten years previously.

A strong, although as yet unsuccessful, effort is making to prove that cancer is also caused by a parasite. At any rate the trend of professional opinion questions the capacity of hereditary transmission which was once ascribed to it. Here the pathological ignorance of the laity works to their detriment, for any fatal tumor is apt to be called by them a cancer.

(*d*) We stand on much firmer ground when we come to the occupation of an applicant, as this can seldom be disguised or concealed. Some occupations are so hazardous that no company will insure the participants

[1] "An Attempt to Measure the Extra Risk Arising from a Consumptive Family History." Journal of the Institute of Actuaries, vol. xxx.

in it at the regular rates. Good companies rigidly exclude such persons as brakemen, aeronauts, bartenders, etc., simply because the risk in them is too great. The mortality in these classes is so great that it would be unfair to the other members of the company. Among occupations which stand highest in point of longevity are those of farmers and ministers. Physicians, I regret to state, have not a longevity above the average. Modesty forbids me to mention the altruistic qualities which cause this sacrifice. Another factor in the material environment is the place where the applicant lives. Some countries are so lawless that life insurance and they are incompatible. One can hardly imagine for instance any life-insurance company doing business in Crete or Armenia or Upper Egypt. Again, some countries are so unhealthy that the mortality far exceeds what we regard as proper. In such countries insurance at the regular rates would be preposterous and is not attempted. In some of them an actuary can determine the premiums suitable to this increased mortality. Insurance can then be effected without detriment to the other members of the company.

THE CORNEA AND THE CAUTERY—THE USE OF THE GALVANO-CAUTERY IN ULCER OF THE CORNEA.

BY C. S. KOLMAN, M.D.,

IN August, 1895, *The Hospital*, a well-known English medical journal, after quoting from the address of Sir William Broadbent before the annual congress of the British Medical Association, to the effect that new remedies are added every day for the benefit chiefly of those who do not know how to employ the old ones, observed that the story of King David's sling and stone has a priceless application in medicine.

Whenever in any important respect the treatment of a disease may be believed to have been brought to perfection, the evolution of the method and its technique are worthy of record; until universally adopted the lack of novelty does not render the matter too trite for our consideration. To such perfection do I believe the management of corneal ulceration has been brought. Of necessity, a subject so selected—namely, one disease, one remedy—is restricted; it is another application of "King David's sling."

Twenty-five years ago, October 28, 1872, at the meeting of the San Francisco Medical Society, Dr. Martinache exhibited two patients, a child and a woman, whom he had cured of corneal ulcers by the application of the actual cautery, an iron probe at white heat. The *Pacific Medical Journal*, which reported the society's proceedings, questioned not the success of the treatment, but Martinache's claim to priority, stating that the cautery had hitherto been extensively used and certainly so in the treatment of pannus. Dr. J. H. Claiborne, before the New York Academy of Medicine, April 20, 1891, in an address upon the use of the actual cautery in infected ulcers of the cornea, gives the bibliography of the cautery in diseases of the eye from the time of Hipocrates, who is credited with using it to destroy growths on the inner surface of the lid. Dr. Martinache, however, appears to be entitled to the credit of first directing attention to the value of the cautery in affections of the cornea. Perhaps the application in other conditions, in trachoma, in fistula of the tear sac, etc., a revival of ancient methods of no particular utility, served to divert the attention of the profession from the specific value of the cautery in ulceration of the cornea. Claiborne stated that Martinache's discovery was adopted in Europe more generally than in America, and that the advocates of his method (in 1891) were comparatively rare in this country. The statement hardly holds good to-day. Claiborne advocated Martinache's method in infected ulcers, which he defined as the "serpent ulcer," the deep-seated, perforating ulcer which may discharge pus into the anterior chamber, and the rodent or superficial wandering ulcer which destroys the epithelium of the cornea.[1] We find advocated at this time the crude device of Martinache, platinum being substituted for iron, but the probe was heated in the spirit lamp and quickly, no doubt deftly, carried at a glowing heat to the ulcer. It was a question whether the probe should be held there until cold—a question determined in the negative by Claiborne, who deprecated the galvano-cautery on account of the increased radiation of heat and the distance of the glowing point from the surgeon's hands, thereby making accurate application more difficult. All this is referred to as to the great credit of Dr. Claiborne, who fully realized the utility of Martinache's method and practised it in those cases of corneal ulceration which were least manageable, albeit with appliances very crude and terrifying to the patient as compared with the means to-day at the command of the surgeon.

With an ophthalmic practice by no means large enough to provide many cases annually of diseases less common, with glaucoma, iritis, or even strabismus matters of anything but daily recurrence, it is my fortune to see a large number of corneal ulcers. The limitation of the hour would render impossible a recital of all seen during the past year, and I will briefly refer to only two or three recently treated at the Waterbury Hospital, as illustrating the efficacy of the cautery. For the purpose of such illustration, they are the better because long neglected, attended by destruction of almost the entire pupillary area, and by extension to the deeper tissues of the eye.

April 12, 1897, G. M——, three years of age, was referred to me by Dr. Axtelle, under whose observation, not treatment, the boy came. The history was of severe inflammation, photophobia, and neglect for a year. The condition on examination was ulceration involving the entire pupillary region, extending about half through the cornea; iris implicated, contracted, and glued to the lens. The boy was chloroformed on that same day, and the ulcerated tissue burned away with a delicate platinum point and without perforation of the cornea. His recovery has been immediate, rapid, and continuous. Slight opacity and a slight facet remain. Notwithstanding the iritic adhesions which formed during the long period of untreated inflammation, the eye will be a useful one, although it is as yet too soon to determine what degree of visual power will be preserved. This, however, does in no way militate against the fact of a rapid recovery, which began as soon as the ulcer was converted into a corneal burn.

April 14, 1897, Mrs. L. L——, fifty-three years of age, of Southbury, was sent to me by Dr. Shepard. She had suffered for many months with violent pain, relieved only by narcotics. The treatment of the eye had been wholly neglected. The pupillary area was occupied by a deep-seated ulcer, involving almost the entire thickness of the cornea, obscuring the border of the discolored, contracted iris, and pus was collecting in the anterior chamber. Any result that should relieve from further suffering and enable her to resume her occupation as a nurse was felt to be a good one, and this without hope of vision in the eye, so long and so extensively ravaged. Under cocaine the ulcer was thoroughly burned down with the galvano-cautery; at the edges first, on account of its depth; then in the

[1] New York Medical Journal, May 2, 1891.

centre, until a spurt of aqueous humor indicated that the cornea was perforated. The operation was painless until the tension was reduced by escape of fluid from the anterior chamber. A pressure bandage was applied, and she was put to bed for a few hours. Pain soon ceased, and the subsequent progress and improvement were as rapid as though it had been a healthy eye instead of one ulcerated for months that had been cauterized. In ten days the patient was sent home, eye nearly free from irritation, pus absorbed from the anterior chamber, with moderate opacity and a slight facet. The iris is moderately dilated under atropine, irregular in form, permanent adhesions having formed during the neglected progress of the disease. However slight may be the visual power regained in this case, the incalculable advantage derived by the substitution of a corneal burn for the chronic spreading dissecting ulcer could not be denied.

A third case may sufficiently illustrate the utility of cauterization of the cornea. December 27, 1896, an infant of twenty-two months was referred to me with a letter from Dr. St. John, of Hartford, from which I quote: "R. F——, whom you saw a year ago, has been brought to me, and I find: right eye, corneal abscess central; left eye, keratitis involving whole cornea and rather superficial. No atropine has been used up to now, though I learn that you gave atropine ointment a year ago, but it was used only three or four times. I have given a very bad prognosis for right eye, and a fair one for left eye, provided the child is cared for." It appeared upon inquiry that I had seen the child once about a year before, while it was suffering from phlyctenular conjunctivitis; immediate recovery not ensuing, the treatment advised was omitted after a day or two, and the case practically neglected for a year, during which time irreparable damage to the right cornea occurred. After cauterization improvement was immediate, and the case was discharged in two weeks from the hospital, where it was sent from distrust of home treatment. The resultant opacity has been far less than was anticipated. On May 7, 1897, four months later, the child came to me again, with a very threatening ulcer of the cornea of the left eye. The mother very gladly saw me destroy this with the cautery, and expressed herself as willing to take the child again to the hospital, which indicates the educating effect of experience. To-day the eye appears to be doing well, under the care which the mother has learned to give it.

Less severe instances of corneal ulceration, in which recovery has occurred entirely without opacity, can be cited in any number, but it appears that the three reported, all long neglected, and in which useless unsightly eyes were to be looked for by reason of the unfavorable conditions, make most apparent the specific value of the cautery. I am sorry not to have these three cases here for you to examine. The hour and the place are somewhat unsuitable for very young subjects, but the woman from Southbury has consented to come here, and perhaps one will answer as well as all. That the opacity of the cornea is greatest in this case is not to be wondered at, when we reflect upon the rapid absorption often observed in very young subjects.

To illustrate the tolerance of the cornea, I will ask you to examine that of a dog, whose right eye I punctured a week ago, carrying the redhot platinum point into the anterior chamber. Dr. Bland, to whom I am indebted for our subject, which he anæsthetized for this purpose, states that the animal appeared to suffer no subsequent inconvenience. You will see that the restoration is complete. A faint opacity only remains, which will evidently wholly disappear.

The perfected apparatus for cauterization of the cornea is before you. The platinum point or electrode is about one-half inch in length from its attachment to the handle. It is of wire, No. 12 or No. 14 gauge, *i.e.*, is somewhat over one-one-hundredth inch in diameter. It is retained at any desired heat by regulation of the current at the rheostat; radiation of heat is reduced to a minimum, and is far less than from a probe sufficiently large to retain the requisite heat during transferrence from the flame to the cornea. The hard-rubber handle is two and one-half inches long, and weighs one-fourth of an ounce: it is more lightly held in the fingers than a penholder; it is made without a spring or current interrupter, because the requisite pressure deflects the aim of the operator and makes more difficult the application of the platinum point at the exact spot desired. The connection is therefore made by pressing a spring, on which the foot rests. The cautery handle was made to my order about five years ago. The rheostat is a Gish rheostat; by it the degree of incandescence desired is previously fixed. The platinum point can be placed while cold against the ulcer, and instantly heated to the previously determined degree upon completing the circuit. The electric current is the Edison current of one hundred and ten volts.

My conclusions may be summarized:

To cure quickly and surely, cauterize.

Unless inevitable from previous destructions of tissue, opacities do not result.

Heat radiation is minimized by the galvano-cautery and the rheostat.

Cocaine anæsthesia is perfect and applicable except for young children.

With the electrode in contact with the cocainized cornea before the electric current is completed, cauterization can be effected without the knowledge of the patient.

THE BIPARIETAL DIAMETER AS A SYMPTOM AND DIAGNOSTIC CRITERION OF TUBERCULOSIS.[1]

BY MARK I. KNAPP, M.D.,

NEW YORK.

THEORY led me to the very interesting and highly important observation of the peculiar formation of the head in tuberculosis, which is either flat from side to side, or of a somewhat triangular form with the base corresponding to the occipital bones. However, it must not be understood that tuberculosis modifies the contour of the head which has previously been of a different shape. Speaking thus of what appears to be a pathological condition, the question arises: Which is the normal head? The word normal has a relative value, and what is normal in one case may be abnormal in the other. While the aquiline nose is normal to the Roman, the Greek one is typified as straight. My technical subdivision of the shape of the head is into three classes: The globular, the convexo-parietal (wide biparietal), and the plano-parietal (narrow biparietal).

These three conditions may be recognized either by the touch or by vision, and, best of all, by the ordinary hatter's conformator. The first class I shall omit in this paper. In running our palms along the parietal bones of any person from before backward, we perceive in the convexo-parietal (wide biparietal) (Fig. 4) abrupt eminences, corresponding to the parietal eminences, which perception is absent in the plano-parietal (narrow biparietal) head. These abrupt eminences may be present only on one side or on both sides, in which latter case they may be developed either equally on both sides or unequally. In the plano-parietal (narrow biparietal) head the examining

[1] Read before the New York County Medical Association, June 21, 1897.

palm perceives either no irregularities at all—the contour of the head (Fig. 1) running smoothly, uninterruptedly, almost in a straight line from before backward—or it may perceive apparent eminences (Figs. 2 and 3). These eminences, however, are only apparent, and on further examination they will resolve themselves into well-developed sutures of the contiguous bones; they are not abrupt, as are the eminences in the convexo-parietal head. These latter cases give the triangular-shaped head (Fig. 2). The conformator shows this best.

The statements just cited are substantiated by a few hundred cases, of which four hundred and seventy-seven were collected at the following hospitals of this city: St. Joseph's Hospital, Montefiore Home, Metropolitan Hospital, and City Hospital, in which hospitals I have taken only those cases where a diagnosis had been positively made. I have taken them as they came, from bed to bed, without selection. In all those cases I have found only seven exceptions. Neither are there included in this number about fifty or sixty consumptive women also seen at the hospitals, all of whom had the characteristic plano-parietal head, but whose shape I did not care to take, owing to the interfering hair.

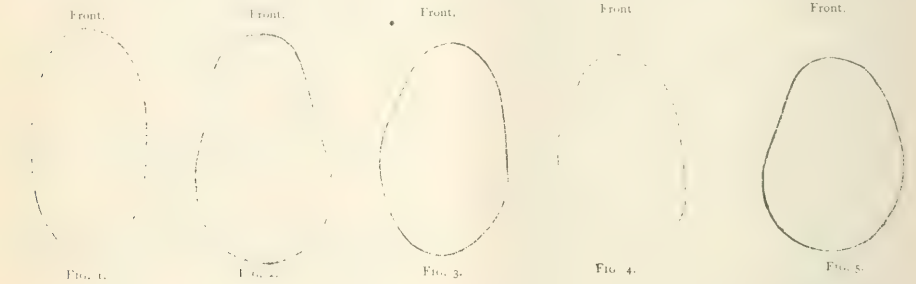


Fig. 1. Fig. 2. Fig. 3. Fig. 4. Fig. 5.

Now, taking for granted that in all cases of tuberculosis the biparietal diameter is narrow (plano-parietal head), what does it signify?

We are confronted with two facts, which certainly allow of a deduction that involuntarily forces itself upon us. On one hand we have the constant or almost constant association of pulmonary tuberculosis with a plano-parietal head, and on the other the plano-parietal head which is the product of physiological chemistry. Borrowing from algebra, we find that if *a* equals *b* and *b* equals *c*, the deduction therefrom is that *a* must equal *c*. May we not draw like conclusions in medicine? If tuberculosis is associated with a plano-parietal head (narrow biparietal diameter), and if the respective size of the biparietal diameter be caused by physiological chemistry, could we not, as in mathematics, conclude that tuberculosis and the plano-parietal head are dependent upon, caused by the same chemical agents? Such conclusion seems reasonable. And again, if tuberculosis be caused only by chemical products and if it be found only in a certain class of persons—viz., the plano-parietals—could we not furthermore conclude that tuberculosis could hardly be communicable or infectious? Why should the tubercle bacillus have selected just the plano-parietals? This is contrary to all scientific reasoning. Differing only in the dose, morphine kills all; neither do arseniuretted hydrogen and hydrocyanic acid know of exceptions as regards the biparietal diameters—both are fatal; a little more for one, a little less for the other—there is no immunity in any of these cases. Why should not its analogue hold good with regard to the tiny tubercle bacillus? As an answer, we are given the inefficiency of either the quantity or the soil. But pertinent reasoning refutes this by the very observations and statements of the same authorities. The floors, the ceilings, the walls, the mats, the draperies, the very air, our investigators say, swarm with that deadly bacillus, and yet we find people undisturbedly occupying the same apartments for weeks, months, nay, for years, during which time tons of bacilli must have been inhaled. As to that highly ductile expression of "favorable soil," are there not abundant examples of cured diseases in the midst of tuberculous surroundings? Of course, the deductions above are alluded to only as possibilities; they need further proofs. The further inference to be drawn from the plano-parietal head is that the foundation for tuberculosis is prepared for the individual either *in utero* or in early life.

The several hundred almost exceptionless cases have satisfactorily proven to me that not only is the association of a plano-parietal head in a disease important for diagnostic purposes, but that such an association is a most trustworthy symptom of tuberculosis, not only of the lungs but in general, no matter of what organ. Pathological symptoms, refer they to the respiratory organs or to the urinary apparatus, refer they to some derangement in the brain or to some hidden lesion of the tibia, if the individual have a plano-parietal head and there be no excess of urates in the urine, the lesion is a tuberculous one, whether the tubercle bacillus be present or not. Syphilis, which I have not yet studied in this relation, may possibly claim exception. Thus, not only must bronchitis associated with a plano-parietal head be looked upon as such, but as the possible precursor of phthisis.

Four cases, three at the City Hospital and one in my own practice, strikingly illustrate this assertion.

Case I.—John G——, forty years of age, came to the hospital, and the diagnosis then was chronic bronchitis; now phthisis is found.

Case II.—Coyle, thirty-eight years of age, came primarily with nephritis, but when the shape of head was taken there were positive symptoms of phthisis.

Case III.—Dennis S——, forty years of age. His left foot was amputated some years ago. At the time of my measurements he was at the hospital for pulmonary phthisis.

In all these three instances the heads were of the plano-parietal type. (I have not yet gone into the previous histories of consumptives; these histories were volunteered by the patients.)

The fourth case was in my own practice. Mr. Max K——, twenty-four years of age, came to me to be examined for admission into a society. His plano-parietal head caused me to subject him to a rigorous physical examination of his chest, which substantiated my suspicion. I rejected him and told him the reason. This caused that young man to consult other physicians, who seemingly corroborated my diagnosis, as they also told the patient, after very careful examina-

tion, that his lung was affected, not yet, however, admitting tuberculosis without bacteriological proof, much to the surprise of the patient, who claimed never to have had anything which should call his attention to the lungs. After having heard the opinion of these physicians, he came back to me for treatment, when, questioning him about his habits, he told me that for the last three years he had been having daily two or three watery, odorless movements of the bowels. Now in the absence of symptoms of nervous troubles and in the positive absence of syphilis, which the subsequent treatment also proved, and with the presence of consolidated spots in the lungs, was not that chronic diarrhœa tuberculous in character or at least strongly suspicious of tuberculosis?

As a symptom, the respective development of the parietal eminences has proven of very high value in my researches and observations; it is the ever-ready and unconcealable betrayer of men's constitution. In my own practice it not only affords evidence of tuberculosis, but gives the key to the entire nature of the patient, the key to his likes and dislikes, to his predilections, and chiefly to his diet.

Now, does the fact that a man has a plano-parietal head mean that such a man either already has or that he of necessity is doomed to tuberculosis? No, decidedly not. The plano-parietal head, the narrow biparietal diameter, as a diagnostic criterion of tuberculosis, is of importance only when a pathological condition makes itself evident—no matter of what organ—and this is not associated with excess of urates in the urine. In fact, the centenarians and the athletes recruit themselves, so far as I have studied them, from the plano-parietals.

To sum up, my researches lead me to the following conclusions: The plano-parietal head is a very valuable symptom of tuberculosis without regard to the presence of the tubercle bacillus, if excess of urates does not accompany the disease; secondly it is found only in a certain class of persons, not in all, and that consequently tuberculosis can be neither infectious nor communicable; and thirdly, and most important of all, it proves that the foundation for tuberculosis is laid in very early life, and that therefore we must direct all our efforts to watching and guiding the infant life if we want to save the adult from tuberculosis.

In conclusion, I wish to thank all the gentlemen connected with the several hospitals, and especially Dr. C. M. Cauldwell and Dr. George T. Stewart.

280 Broome Street.

Is it Ever Impossible to Pass a Catheter through the Urethra into the Bladder?—Dr. Buckston Browne discussed this question before the Harveian Society at a meeting held April 1st. He thought that it was never impossible to pass an instrument, even in the worst cases of stricture of the urethra, unless the urethra had in some part of its course actually ceased to exist. If an instrument was once passed, the case could be brought to a successful issue without any perineal incision, and, that being so, the patient was saved all the risks of hemorrhage, and of that terrible misfortune a perineal fistula. In the most severe cases of prostatic enlargement the urethra was simply tortuous. The difficulties were fully described, and instruments were shown by which they could all be overcome. In no prostatic case was it allowed that the urethra was impassable by instruments, and therefore there was rarely any real need for any form of prostatectomy or for castration. All the other forms of urethral obstruction were discussed, and the question which formed the title of the paper was answered emphatically in the negative.

SUNSTROKE, OR THERMAL FEVER, AND HEAT EXHAUSTION; THEIR TREATMENT THROUGH THE NERVE CENTRES AND THE LUNGS.

BY BEVERLEY OLIVER KINNEAR, M.D.,

NEW YORK.

If any measure acting as a preventive of heat exhaustion and sunstroke, which is also rapidly ameliorative and curative at the time of the attacks, can be discovered, the medical profession and the public will have a double control of these diseased conditions, by the ability to ward them off as well as to restore the patient to health speedily, and thus put a check to those trying and weakening effects so often visible for months and years after an attack of sunstroke or thermal fever in particular. It is with the full belief that I possess the secret of such a treatment that I now lay the subject before the profession.

Heat Exhaustion.—Nearly every one who has been compelled to remain in large cities during hot summers is perfectly familiar with "heat exhaustion." The sense of prostration, both mental and physical, the cool or cold surface of the body bathed in cold perspiration, the nausea or actual vomiting, the restlessness accompanying the symptoms, the pale face, the feeble pulse, and the tendency to faint, are probably known to all those who have endured great heat while in active professional or business labor.

It has been the writer's own experience many times during the past sixteen years, after a hard day's work in the heat, to arrive home suffering in just this way; but during the period mentioned, by the application of the measures about to be considered, he has invariably, when so seized, been enabled within an hour to feel as comfortable and refreshed as if he had not succumbed to the heat in consequence of his active mental and bodily labor in it.

And not only this, but by the use of the same means he has been enabled to obtain refreshing sleep during the hottest summer nights, and thus be ready for the work of the next day. Again, very many patients have expressed to him the relief obtained by its use, and particularly the sense of refreshment and rest when it has been applied during heated terms. This treatment is the application of cold over the spine; and by it we can dry up the cold perspiration, warm the whole surface of the body, quiet the muscular restlessness, stop the nausea, strengthen the pulse, reacquire mental and muscular vigor, and thus recover from the prostration and faintness.

By the local action of the cold on the nerve centres the excess of blood is expelled from them, and the symptoms which are due to this excessive circulation in the nerve centres disappear; while the action of the cold locally upon those nerve centres, causing contraction of the arteries, expels the blood from them, and the arteries throughout the body dilate, causing the pulse to recover its strength and the system its vigor, in consequence of the restored normal distribution of the blood.

The effect is delightful to the person treated, who in a short time experiences a renewed sense of vitality. I have induced these effects in cases of heat exhaustion hundreds of times, by this application, and am convinced that if business and professional men would supply themselves with a bag of the right kind and use it once or twice a day in hot weather, they would find themselves, if not impervious to the effects of heat, yet enabled to do their work with more vigor and with greatly lessened danger from either heat exhaustion or sunstroke.

For the average person the bag should not be more than twenty-two inches long, and four and one-quarter

inches wide, because a wider bag will chill the body, and a longer one will pass below the portion of the spinal cord in which central nerve cells are placed. These bags are made of rubber, and are fastened with a clamp at the top. They are divided into three compartments, for two reasons: in order that the ice placed within them may not all float to the top, when the bag is applied over the spine, and thus make a greater degree of cold over one section than another; and also that one, two, or three of the compartments may be used, as may be necessary in the treatment of the case at hand.

I am of the opinion that excessive heat of the atmosphere, especially moist heat, which prevents the natural evaporation from the skin, draws the blood in excess into the nerve centres; and in heat exhaustion, those centres in particular which preside over the vasomotor functions. In consequence of the hyperæmia of these centres, the blood leaves the surface of the body and goes to the internal organs, including the nerve centres in the spinal cord, giving rise to the muscular restlessness, the cold perspiration, the nausea, and the faintness. If this be so, it can be easily understood how cold applied locally over the spinal cord and the knots of nerve tissue upon each side of the spine, known as the sympathetic ganglia, will act to overcome the condition by expelling the blood from the nerve centres, preventing them thereby from exercising their function abnormally. That the treatment does so there is a great mass of evidence from its use in a large variety of diseased conditions. The temperature of the body falls very low in severe cases of heat exhaustion, and the usual treatment now adopted by the regular profession is the use of external heat by hot-water baths, the hypodermic injection of atropine, strychnine, and digitalis, in order to stimulate the heart and start the general circulation; but these remedies are often insufficient either to ameliorate or to cure in serious attacks; while the cold over the spine will always act, and act promptly, and it can be aided in its action by applying hot-water bottles to the surface of the body until the circulation has recovered its full strength and the patient his normal tone. Besides this, it is much more easy of application than hot baths in cases of prostration, and it is not at all distressing, but at once refreshing to the sufferer.

In filling the ice bag with finely chopped ice, the lower compartment should be first filled to the bottom of the second, then the second one to the bottom of the first, and lastly the top one to the line of the thick piece of rubber across which the clamp is placed. The clamp should then be screwed tightly on and the bag held in the warm hands for a few moments, to expel the latent air that is held in the ice, and directly the air bulges out the bag the clamp should be unscrewed sufficiently to enable it to escape entirely, and when this is done the appliance is ready for use, and may be placed directly along the centre of the spine, from the line of the shirt collar to the full extent it will fall down the spine. It may be kept on—being refilled every two hours—until the circulation is fully re-established and the sufferer has recovered a good modicum of strength; it may then be removed, and used one hour in every four, until the patient feels as well as usual. During the rest of the hot season, and to prevent further attacks, it would be well to use a bag once a day for an hour until the cool weather sets in; taking care that during the use of the treatment the bowels are kept freely moving and well cleared from all fecal matter by the biweekly use of large enemas of soap and hot water.

Meat, except upon cool summer days, is hurtful to everybody, and an unirritating and farinaceous diet should be enjoined.

Sunstroke, or thermal fever, is a condition induced by heat which is just the opposite of heat exhaustion, as it is accompanied by very high temperature, apparent expansion of the arteries throughout the system, flushed face, eyes injected with blood, and congestion of the brain, with either total unconsciousness, delirium, or mental confusion. There may be convulsions, there is often vomiting, and frequently there are diarrhœa and intense muscular restlessness.

The direct action of the sun is not necessary to induce these symptoms, but simple exposure to long-continued and great heat. The worst attacks frequently take place at night, and we believe that one of the causes of this is that the patient goes to bed with an already congested brain, and, the prone position enabling the excited heart to send more blood to the brain with less effort than in the erect posture, the arteries in the brain expand still more widely than they have expanded in the daytime, and the so-called sunstroke may be then more likely to result.

The breathing is apt to be irregular and labored, and at times stertorous, denoting to our observation excitement of nerve centres, and some hyperæmia of the lungs.

The sequelæ of this disease denote that there is left behind a condition of cerebral hyperæmia, which may become chronic and interfere for the rest of the patient's life with his work and his enjoyment. These after-effects consist of pain in the head, feebleness of memory, heat of the head when exposed to any unusual heat in winter as well as in summer, stiffness of the muscles of the back of the neck; and in recovery in very bad cases there may be symptoms of chronic cerebral inflammation, also a tendency to convulsions.

The object of treatment is of course to lower the temperature as quickly as possible, and the chief measures now adopted are the cold bath, rubbing with ice, perhaps blistering, shaving the head, and the internal use of antipyrin.

There is no doubt that in thermal fever the brain is intensely congested and the circulation at the same time is very active; thus the ice to the head, which is also always used, is an excellent measure. But all of these together cannot compare, in my estimation and in my experience, with heat applied over the last four cervical and first four dorsal sympathetic ganglia, to overcome the congestion in the head and brain by contracting the dilated arteries in these regions.

The effect of heat so placed in a double-columned hot-water bag is at once to begin to lower the temperature, cause profuse perspiration, slow the rapid action of the pulse, and restore the patient to consciousness, if in a state of stupor; or to his senses, if delirious.

One case in New York, under my own care, I treated by this application with immediate success. The patient was suffering from pronounced sunstroke; his temperature was 105° F.; the pulse was full and bounding at the wrist and in the temporal arteries; the head was very hot, the face was flushed, the eyes were injected, and the man was in a condition of semistupor. Heat was applied over the lower cervical and upper dorsal vertebræ, with the effect that in three hours the temperature had fallen almost to normal, the pulse was quiet, the man was quite rational, and had enjoyed some sleep. The application was used for half an hour every third hour through the night, and at my morning visit I found the attack quite conquered.

In a second case, treated by correspondence, in Elizabeth, N. J., the patient, a physician, after treatment for several days, found that he was going down hill, with the fever unsubdued and the head symptoms growing worse. His wife, a very intelligent woman, treated him with the double-columned hot-water bag,

and in half an hour the temperature began to fall and he broke out into a profuse perspiration. Twenty-four hours' use of the bag, at stated intervals, sufficed to relieve him completely.

A third patient was the managing editor of one of the large New York religious papers, and his case is an exceedingly interesting one, because, although it was chronic, it yielded readily to treatment by the double-columned hot-water bag. Having been overcome by the heat several years ago, and laid up for some time in consequence, he apparently fully recovered, but during the following summer, directly the very hot weather set in, he was obliged to rest several days by reason of congestion of the brain, and toward the end of the season another attack followed. These attacks took place each season, until, in 1892, during one of them he put himself under my care. He was in a semiconscious state when first visited, with a very red face and injected conjunctivæ, and could be aroused to talk only for a few minutes at a time, when he would relapse into a state of partial stupor; there was no rise of temperature, but the condition was evidently dangerous.

The double-columned hot-water bag was at once applied over the proper segment of the spine, and before half an hour had elapsed, the face had lost its flush, the mind became more active, and the redness of the eyes disappeared.

In twenty-four hours the patient resumed work, and he has had only one return of the trouble since, when the prompt application of the hot-water bag speedily relieved him.

It is the writer's opinion that if every hospital surgeon in the large cities would supply himself with a number of double-columned rubber hot-water bags, eight inches long and four and a quarter inches wide, for prompt use in cases of thermal fever, he would have much less trouble in treatment, and much more speedy recovery from such seizures; and the unpleasant sequelæ of the attacks would be to a large extent prevented.

It is my conviction that the cause of the high temperature in thermal fever is intense hyperæmia of the brain and the spinal nerve centres, but particularly of the brain, overcoming in this organ almost completely the normal contracting power of the sympathetic ganglia; therefore the most energetic and efficient treatment is to stimulate the cervico-dorsal sympathetic centres, by means of heat, to such powerful action as to overcome the abnormal action of the cerebro-spinal vasodilator centres, thus contracting the arteries in the congested areas, distributing the blood in normal quantity throughout the body, and so not only quickly subduing the dangerous symptoms, but also restoring the natural vigor of the patient.

As the sequelæ invariably denote hyperæmia of the brain and upper body, I advise the use of the spinal ice bag, filled in the two upper compartments and applied from the line of the shoulder blades down the spine to the line of the waist. This treatment will dilate the arteries in the lower body and induce healthy metabolic action in the digestive and secreting organs, give vigor to the muscular system, and at the same time withdraw the excess of blood from the brain and upper body, and allow the unduly expanded arteries in these regions to contract to normal. The hot-water bag may also be used once or twice a week over the cervico-dorsal region so as to assist in the contraction of the arteries required to accomplish complete recovery.

By these measures the after-results of sunstroke, such as the inability to bear heat without cerebral discomfort or pain, the headache, the failure in general strength, the stiffness of the muscles of the neck which sometimes results, the vertigo, loss of memory, inability to concentrate thought, and the nervous irritability, may be readily and speedily overcome; and the patient will be able to resume work, and enjoy life as formerly.

There is another remedy which we find most efficient in preventing and, if they are present, rapidly checking the disagreeable symptoms induced by heat, and that is the inhalation of oxygen. It will almost instantly remove the fulness of the head or the headache induced by heat; it will dry up at once the moist perspiration, warm the body, and invigorate the muscles; and the sense of glow from its use, with the increased feeling of vitality, is most agreeable and refreshing; it deepens the natural respiration for some hours after its use, and it makes the pulse full and incompressible. I speak here from personal experience.

I would also strongly advise its use to overcome the after-effects of thermal fever; to relieve the headache, strengthen the digestion, stimulate the heart, and increase nutritive processes in general; and, if it were used daily by those who have a tendency to "blood to the head" in hot weather, I have no doubt that rapid and continual relief will be obtained.

Oxygen to be efficient must be pure, and it must be combined with a gas of lighter specific gravity also, in order to obtain successful results from its use, as pure oxygen alone is too dense in its specific gravity for absorption by the pulmonary capillaries, and gives rise to too great local oxidation, if the mucous membrane of the bronchial tubes is at all irritable. The gas which has been found most efficient for the dilution of the oxygen is nitrous monoxide; and the formula used by the London Oxygen Hospital is considered by all authorities upon oxygen as the best. It consists of two parts of pure oxygen, one of nitrous monoxide, and one per cent. of electrified oxygen, or ozone, to keep it fresh.

In hot weather it is best for all men to live on a light and unstimulating diet; to avoid in every way either great mental or bodily fatigue, as well as unusual excitement from any cause, and all excesses in any form whatever.

Following such rules in summer time is in itself a great preventive of attacks of either heat exhaustion or sunstroke; therefore the person who is temperate in all things during the hot season has the best chance of escape.

In conclusion I would recapitulate as to the chief causes of thermal fever and heat exhaustion. The causes of the latter I believe to be hyperæmia of nervous centres, but especially of the sympathetic ganglia; as only by excessive function of these special knots of nerve tissue can the arteries become contracted throughout the body and the temperature fall below the normal.

In sunstroke we have excessive circulation in and increased function of nerve centres, but so great is the stimulation of the vasodilator centres that the function of the vaso-constrictors or sympathetic ganglia is almost completely overcome, especially those controlling the circulation in the upper body, head, and brain; so that there are both an active circulation in these parts, in most cases, and excessively dilated arteries, inducing excitement of the brain and confusion of thought, but if of more serious form causing stupor or coma.

The best treatment for sunstroke is to overcome the cerebro-spinal excitement by contracting the arteries, through the agency of the sympathetic; and for heat exhaustion, to expel the excess of blood from the spine and sympathetic ganglia, by means of the spinal ice bag, thus restoring the general circulation and relieving the excited centres of their congestion.

The temperature of the water used in the spinal hot-water bag should not exceed 120° F.

202 West One Hundred and Sixth Street.

SOME PRELIMINARY OBSERVATIONS ON THE APPLICATION OF THE KASHIDA-OGATA MEDIUM TO THE EXAMINATION OF DRINKING-WATER.

By ARTHUR J. WOLFF, M.D.,

AND

JOHN B. McCOOK, M.D.,

HARTFORD, CONN.

The recently published observations of Dr. K. Kashida,[1] under the direction of Professor Ogata, at the Royal University of Tokio, Japan, on a new and original medium for the differentiation of the bacillus coli from the typhoid bacillus, attracted our attention to its probable usefulness for the detection of these organisms in drinking-water. The very distinct reactions which can be produced by the medium, and the rapidity with which the necessary operations can be carried on, render it a promising field for investigation.

Preparation of the Medium. — Production of the litmus solution: Twenty grams of common litmus are completely exhausted with water; this liquid is carefully filtered; the resulting filtrate is now evaporated on the water bath to an extract, the latter being neutralized with acetic acid. The evaporation is now carried on until all the acid is driven off, and the resulting extract is then exhausted with a large quantity of ninety-five-per-cent. alcohol. The alcohol removes all the acetate of potassium formed and at the same time the red coloring matter of the litmus. When the alcohol comes through the filter devoid of red color, the blue residue left on the filter is allowed to dry, and then distilled water is poured upon the filter in such amounts as to produce a saturated solution of blue-litmus extract. This is preserved in flasks properly plugged with cotton and carefully sterilized. A one-and-one-half-per-cent. solution of agar in neutral bouillon is now prepared, and to this are added two per cent. of milk sugar, one per cent. of chemically pure urea, and when these are completely dissolved, thirty per cent. of the above litmus solution; the mixture is now carefully filtered and sterilized. This completes the Kashida medium. Before the addition of the litmus the reaction of the material is to be carefully tested and properly corrected, as upon this depends to some extent the accuracy of the results. With the medium as above prepared, one can very readily confirm the conclusions of Kashida in the article mentioned.

Experiments with our Hartford water supply have been productive of surprising and satisfactory results, which point to this medium as a possibly valuable addition to our methods of examination.

Cultures were first made with the tap water upon Petri plates, and these incubated at the body temperature, no change being observed in the color of the medium, except that a colony was discovered which produced a deeper blue than that of the surrounding medium. An examination of this colony showed it to be a pure culture of a bacillus which at the present time is being completely investigated.

Definite quantities of the tap water were contaminated with coli and typhoid bacilli, both alone and in mixture. The following are some few of the results obtained: One-half cubic centimetre of tap water was contaminated with a loop from an agar culture of typhoid bacilli and a loop from a similar culture of bacillus coli communis; this mixture was plated with about ten cubic centimetres of the Kashida medium and incubated. Examined after the lapse of twenty-four hours, the medium exhibited a distinct acid reaction and a profuse gas formation, as shown by a diffuse mottling of the medium with bubbles. After seventy-two hours the medium commenced to change to a blue color, due to the formation of ammonia during the decomposition of the contained urea. This change did not occur until after seventy-two hours, and at the same time the bubbles commenced to diminish in number and size.

A mixture was made containing one loop each of coli and typhoid from agar, these being placed in one cubic centimetre of tap water and plated with ten cubic centimetres of the medium. In twenty-four hours this showed a marked acid reaction and the production of gas. After the lapse of fifty-four hours no change in color was observed, but decided diminution in the number of gas bubbles. In seventy-two hours a beginning alteration of color to blue was marked, and during the next twenty-four hours the change to deep blue was complete.

Ten cubic centimetres of the Kashida medium were inoculated with one-half cubic centimetre of the following mixture: Tap water, fifty cubic centimetres; one loop from agar culture of typhoid; one loop from agar culture of coli bacilli. One loop of this mixture was placed into ten cubic centimetres of tap water and plated. In fifty-four hours this plate showed a marked acid reaction, with profuse gas production. In this there were colonies, some appearing white, while others showed a distinct blue color. (Bouillon cultures of both were made.) After seventy-two hours the blue color had replaced the red, the former being much deeper than in the original medium.

Two specimens were prepared in the following manner: One-half cubic centimetre of tap water was mixed with ten cubic centimetres of the medium and plated. At the end of fifteen hours these plates showed very slight mottling of red here and there, but when examined on a white surface this red coloring was very indistinct. There was a very profuse growth of bacteria on the plates, but no formation of gas bubbles whatever in any of them. After thirty-nine hours they had not perceptibly changed; no gas was to be discovered in either. At the end of seventy-two hours one of these plates showed a loss of the red tint and the production of a yellowish-white appearance in certain zones of the plate. Another specimen showed a still deeper shade of red, but which by transmitted light mostly appeared of a blue color with some few yellowish-white areas.

Other specimens of tap-water were examined in tubes filled with the medium, the results being in no material manner different from those already described. Specimens of water which were known to have been contaminated with sewage were next employed, and in each case the results would seem to correspond with the degree of contamination of the water.

Comparing our results with those obtained with other media, we are led to feel encouraged in the belief that Kashida's medium may have an important future in water examinations. Certain questions, however, have already forced themselves upon us: May there not be other bacteria than the coli bacillus, existing in water, which produce the same changes of color and similar gas formation? Our observations, however, thus far show that in any case in which an atypical reaction occurs, the microscope clears up the doubt in a few minutes without any tedious technical process of isolation.

Bacteriological Laboratory of the Board of Health, Hartford, Conn., August 5, 1897.

The Sightless Ones.—It is stated that there are 1,000,000 blind people in the world, or one to every 1,500 inhabitants.

MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., EDITOR.

PUBLISHERS

WM. WOOD & CO., 43, 45, & 47 East Tenth Street.

New York, August 21, 1897.

THE ELIMINATION OF LEPROSY-BACILLI FROM THE BODIES OF LEPROUS SUBJECTS.

WHILE formerly the view was almost universally held that leprosy is transmitted by inheritance, it had long been suspected that the disease is contagious. It was not, however, until the discovery of the leprosy-bacillus by Hansen, in 1880, that this suspicion became susceptible of scientific confirmation. The rapidity of extension of the disease in those localities in which it was introduced was sufficient to exclude hereditary transmission as the sole agency in its spread. On the other hand, the results of inoculation-experiments have been variable and in most instances of negative character, but the single positive result in the case of the Hawaiian convict condemned to death is sufficient to establish the infectiousness of leprosy. Some authorities have taken an intermediate position, maintaining that leprosy is, like syphilis, transmissible by both contagion and inheritance.

In order to prove the contagiousness of leprosy it would be necessary to demonstrate the presence of the specific bacterium in all cases, its mode of elimination from the body of infected subjects, and its transfer to another and the development of leprosy in the latter. The organism is, however, difficult of cultivation, and definite knowledge has been wanting as to its usual mode of elimination. To clear up some of the doubtful points surrounding the channels through which conveyance of leprosy takes place, Weber (*Deutsches Archiv für klinische Medicin*, B. lviii., H. 4, 5) undertook a careful study of a case that chanced to come under observation. The patient was a cigar-maker, forty-three years old, in whose family history there was no suggestion of leprosy, and who had spent some ten years in the Dutch East India Islands, in the course of which he had come in contact for two weeks with a native officer suffering from leprosy. After an interval of nineteen months following this exposure, lesions of leprosy made their appearance, the patient meanwhile suffering from loss of appetite, which was attributed to the quality of the food; from weakness and sweating, which were ascribed to the great heat; and from occasional bleeding from the nose, which had been present from boyhood. The skin was in various situations thickened and infiltrated, in places the seat of hyperæmia, macules, and pigmentation; there was some glandular enlargement, and in places there were analgesia and thermanæsthesia. In order to determine the presence and the mode of elimination of the bacilli, a systematic bacteriological study was made of all the secretions and excretions, the blood and the fluids of the tissues, the skin, the scales, the hair. The Ziehl-Neelsen method of staining with carbol-fuchsin proved to be the best, and positive results were obtained with blood from a diseased area—that is, bacteria were found in the contents of a blister induced by the thermo-cautery in the skin and in the scales thrown off, in the hair, in the sweat, in the seminal fluid; while bacilli were not found in blood obtained from a healthy area, in the saliva, or in the urine.

From these observations it is obvious that there are numerous channels through which the bacilli may be eliminated, and that the transmission may take place by mediate or more or less immediate contact. That infection is not thus more commonly conveyed than it actually is may be due to the fact that the bacteria thrown off through the channels indicated may be deficient in virulence or that certain peculiarities must first be complied with on the part of the exposed individual. Under any circumstances it may be safely maintained that leprosy is a specific, infectious disease, capable of transmission by more or less direct association of sick and well. It is not known that any form of medicinal treatment is capable of exercising a directly curative effect, but the spread of the disease can be prevented by the adoption of the broad principles of prophylaxis applicable to all of the infectious diseases, namely, isolation of the sick and disinfection of the materials in and with which the causative micro-organisms are eliminated from the body.

TRAUMATIC HYSTERIA.

IN this age of railway travel, when so many persons spend an appreciable portion of each day on a train, the fact that a new group of symptoms has been developed in connection with railway injuries is only in the common order of things. The close relationship of distant parts of the body through the agency of the nervous system makes it unavoidable that prolonged physical pain should cause mental anxiety and derangement of general health, but a trifling injury to the periphery may tend in time to considerable mental disturbance, while psychical shock acting on the cerebral cortex may bring about grave impairment of health. To this class of complaints the name of traumatic neuroses is most commonly applied. In the July number of *Medicine*, Dr. Augustus A. Eshner writes instructively on this subject. He says: "The symptoms of this disorder do not differ essentially from those of hysteria of any other origin, but I have used the term in order to express disapproval of it." And again: "Concerning the intimate nature of hysteria, we can as yet but theorize. To designate the disorder a neurosis adds nothing to our knowledge, and to burden this designation with such qualifica-

tions as functional or reflex or idiopathic or traumatic, in no wise tends to clarify our notions upon the subject of its pathology. In hysteria we have to deal essentially with a defect in the nervous co-ordination, an adequate cause for which can be conceived to reside in the metabolic alteration in the ultimate nervous elements resulting from modifications in cellular nutrition. Such a conception is not in conflict with the alluring theory of the motility of the neuron so ably advocated by Dercum and others, as it is probable that the metabolic processes taking place in all of the tissues are attended with cellular movement." Charcot pointed out that in the vast majority of cases of traumatic hysteria the patient at first thinks he has escaped without injury, because he has felt no immediate ill effects. There would seem, therefore, to be a period of incubation, and in many cases the patient may not develop symptoms for some weeks. The fact is now universally recognized that it is a mistake to regard these symptoms always as imaginary or feigned, and if such a course be followed the treatment is at times likely to be unsuccessful.

THE ABUSE OF HOSPITAL CHARITY.

The abuse of hospital charity appears to be an almost universal evil. From all the large cities of the civilized world comes the wail of the general practitioner that the hospitals and dispensaries are taking from him the means of gaining a livelihood. He cannot compete with them on equal terms. According to the *Journal de Médecine* it has been computed that there are in Paris twenty-five hundred medical men battling with starvation from precisely the same causes as in the United States and Great Britain. It is in London, however, that the abuse of hospital charity has risen to its highest pitch. Statistics show that yearly more than one-fourth of its population are recipients of medical relief. Dr. D. Campbell Black, of Glasgow, in an address on hospital management in Great Britain in general, and in London and Glasgow in particular, referring to London, says that "the hospital system there has reached its apogee of iniquity," and adds "that the system in the virtuous city of Glasgow is in an equally rotten state." It is to be hoped that Dr. Black is somewhat carried away by his feelings and is inclined to exaggerate matters, but that there would seem to be much truth in his statements cannot be denied. A special commissioner of *The Lancet*, who is investigating the subject, reports that abuses do exist to a very large extent, and says that the special hospitals are the greatest sinners. The fact, too, that the "Prince of Wales' hospital fund" has been a partial failure is a proof that there is an uneasy feeling in the public mind in regard to the conduct of these institutions; there are a great many rich persons both willing and ready to give freely, provided that they are satisfied that the money will be judiciously expended. Indiscriminate charity does more harm in the long run than good, and the manner in which London hospitals have been conducted has given rise to the suspicion that there must be something radically wrong in their management. The conduct of the out-patients' department has been characterized by a high English authority as often a complete farce, demoralizing to the people and unjust to the medical profession. For this state of affairs the general public is not wholly to blame. On the medical profession itself, as has so often been shown, a large share of the responsibility rests. Dr. Black insists that in Great Britain the medical men connected with the hospitals are responsible for all the trouble. He makes the sweeping assertion that "the medical profession is the most masterly of all callings in its hypocritical devices to catch the public eye, and to accomplish this it finds in the hospital system the most convenient and popular medium, falsely based as it is on the best attributes of our common humanity, viz., benevolence and compassion." There can be no doubt that it is invariably the object of young and ambitious men to obtain a position on the staff of a hospital, and they are sometimes willing for the sake of the advertisement, with the hope of ultimate gain, to abase themselves before the public and to shut their eyes to all abuses. In London various schemes, for the most part more or less visionary, have been suggested as a remedy, but nothing practical has as yet been put forward. The position is a most difficult one, owing to the many interests involved, and the only remedy lies, in the opinion of *The Lancet*, "in the organization of the medical profession and the simultaneous action of the hospitals."

WHERE QUACKS ARE NOT WANTED.

The Kentucky State board of health has recently gained a notable victory over quackery by securing the conviction and fine of a professor of osteopathy who plied his trade for a time in Louisville. The osteopaths there, as elsewhere, seek to evade the medical-practice law by setting forth the claim that they do not "practise medicine," that is to say, they do not prescribe drugs, perform surgical operations, or set fractures, but simply manipulate the muscles with the hands. This was the plea advanced by an osteopath in Louisville who was charged with practising medicine without a license, in that he twisted and pulled and flexed the leg and thigh of a poor little martyr with hip disease, or, in the words of the opinion of Judge Thompson, in that "in his ignorance of the fundamental principles of his profession he subjected the child, which was laboring under a tuberculous disease of the hip, to cruel and unnecessary torture, affecting its health and necessitating the employment of a physician to treat it for fever resulting from his inaptitude."

The ruling of the court, which will doubtless serve as a precedent in future cases of the sort, was that "any person who, for compensation, professes to apply any science which relates to the prevention, cure, or alleviation of the diseases of the human body, is practising medicine within the meaning of the statute." On the evidence, the judge found the defen-

dant guilty as charged, and a fine of fifty dollars was assessed against him.

The osteopaths were well provided with money and were ably defended in this case, but, in the face of the evidence brought forward, the conviction of the man was inevitable.

Kentucky has many things of which its sons are justly proud. They claim that it has the handsomest women, the finest horses, and the best whiskey in the wide world, and now, last but by no means least, it has a lot of real doctors, men whose right to practise was honestly come by. To quote from a letter of Dr. J. N. McCormack, secretary of the State board of health: "Our law has now been in operation nearly four years. It has been tested upon every point and so far we have not failed to secure a conviction in each case tried. We convicted the Copeland people, the 'K and K's,' and all other concerns of that kind doing business here, and are able to report that there is not now an itinerant or advertising doctor within the limits of this State." Would that the same could be said of every State in the Union!

News of the Week.

A State Veterinary College has been established at Cornell University in which free instruction in veterinary medicine and surgery will be given to citizens of New York State. In addition to this the authorities of the college will conduct investigations as to the nature, prevention, and cure of animal diseases; investigate the economic questions which concern the more profitable breeding, rearing, and utilization of animals; and produce reliable standard preparations of antitoxins and other products to be used in the diagnosis, prevention, and cure of diseases in animals. Cornell University will administer the veterinary college, appoint investigators, teachers, and other officers, lay out lines of investigation, and prescribe the requirements for admission and the course of study. The university is to receive no compensation for this.

Moscow Delegates Received by the Tsar.—On Tuesday of this week the Tsar received at the Peterhof Palace in St. Petersburg a number of physicians who were on the way to Moscow to attend the International Congress.

Low Mortality in New York City.—The lowest death rate for a week in this city for the past twenty-five years was that for the seven days ending last Saturday. It was 20.09 per 1,000. The first week in August also had a very low death rate, 20.78. This favorable showing is due in large measure to a remarkable decrease in the number of deaths among children. There has never been a year when there was so little cholera infantum. The figures for the five weeks ending July 31st are 2,457 for 1897, and 2,566 for 1896. The reason for the lessened mortality among children under five years of age is to be found in the improved sanitary condition of the streets, in the rigid inspection of milk and the supervision of the dealers by the board of health, and in the absence of any prolonged season of excessive heat.

Medical Schools in Denver.—As we noted in a recent issue, by a decision of the supreme court the Medical Department of the University of Colorado will no longer be permitted to conduct a course of instruction in Denver: consequently the regular course of medical instruction will be given in Boulder for the present, but, as soon as the charter is amended, the medical department will be reorganized in Denver. Many of the former faculty of the University of Colorado have united with the Gross Medical College of Denver, among them being Drs. Clayton Parkhill, Josiah N. Hall, G. Melville Black, and James M. Blaine. To the faculty of the Gross Medical College have also been elected Drs. William N. Beggs, of St. Louis; Lincoln Mussey, of Cincinnati; George Edward Tyler, of Washington, D. C.; Louis H. Kemble, of Denver; Charles Byron Nichols, of Boston; David H. Coover and David D. Thornton, of Chicago.

Dr. Paul F. Munde, of New York, has been elected an honorary fellow of the Edinburgh Obstetrical Society.

Pennsylvania and Maryland Union Medical Association.—The twentieth annual reunion of this society will be held at Highland Park, York, Pa., on Thursday, August 26, 1897. The officers of the association are: *President*, Dr. Joseph Price, Philadelphia, Pa.; *Vice-Presidents*, Dr. C. A. Rahter, Harrisburg, Pa., and Dr. Chas. G. Hill, Baltimore, Md.; *Secretary*, Dr. Roland Jessop, York, Pa.

A Proving of the Bacillus Icteroides.—A physician in Uruguay, Dr. Antonio Quesada, has offered to subject himself to inoculation with the bacillus icteroides in order to prove the correctness of Sanarelli's assumption that it is the pathogenic agent of yellow fever. All attempts to turn Dr. Quesada from his purpose by pointing out its dangers have been unavailing, so that with every precaution the experiment will be conducted in the presence of a few selected physicians, who will carefully note the progress of the case. Dr. Quesada is a robust man, forty-two years of age, who was formerly a surgeon in the Spanish army, serving in the Philippines and in Cuba. He made a deep study of yellow fever while in Cuba, but asserts that he has never had the disease. He professes absolute confidence that the experiment will prove the value of Sanarelli's researches.

Canadian Medical Association.—The thirtieth annual meeting of this society will be held on Monday and Tuesday, August 30 and 31, 1897, in Synod Hall, Montreal, under the presidency of Dr. V. H. Moore, Brockville, Ont.

Disinfection of Sleeping-Cars.—The Louisiana State board of health has decided to disinfect all sleeping-cars coming to New Orleans. All such cars entering the city immediately upon their arrival will be cleaned thoroughly and disinfected under the surveillance of the sanitary inspectors of the board of

health. The towels and bedclothes will be sterilized by steam. The system of disinfection will also be extended to all steamships arriving at that port.

Medical Society of New Jersey.—Dr. D. C. English, president of the Medical Society of New Jersey, has appointed Dr. William Pierson, of Orange, third vice-president of the society, to fill the vacancy occasioned by the death of Dr. John J. H. Love, of Montclair. He has also appointed Dr. William J. Chandler, of South Orange, recording secretary in place of Dr. Wm. Pierson, resigned.

Quarantine Regulations in Costa Rica.—Dr. T. M. Calnek, of San José, Costa Rica, member of the international executive commission of the Pan-American Medical Congress, in a recent communication to the secretary, Dr. Chas. H. Reed, of Cincinnati, states that it is the intention of the government of that country to establish a fully equipped quarantine station with all necessary disinfecting appliances. The necessity for this course is found in the infected condition of practically all of the tropical ports of the Pacific. An efficient inspection service is now maintained at Port Limon under the supervision of Dr. Varela.

A Microbic Cure for Typhoid Fever.—Dr. Hankin has reported to the Indian government the discovery by a young Parsee medical man, Dr. Ghadialli, of a micro-organism to which is ascribed the power of destroying the typhoid bacillus. This discovery was suggested by the fact that, in samples of water sent for examination containing this microbe, the bacillus typhi abdominalis was never found. Hankin has named the microbe after its discoverer, the "micrococcus Ghadiallii." In pure cultures it is harmless to man when swallowed by the mouth, and produces no ill effects when injected into the peritoneal cavity of rabbits and guinea-pigs. It is already suggested that cultures of this micro-organism might be used as a remedy in typhoid fever, as a disinfectant of typhoid stools, and as a purifier of infected drinking-water.

Syphilis and Colds in the Head.—Dr. C. B. Taylor, an erratic physician of Nottingham, has been speaking and writing at length against the measures that are to be again put in force to reduce the morbidity of venereal diseases among the British troops in India. Among other up-to-date views enunciated by this exponent of scientific medicine are that gonorrhœa is an affection of little or no gravity; that a common cold is more dangerous than syphilis, since it "causes one hundred and twenty thousand deaths every year, while syphilis is probably the least fatal of all serious diseases;" that it is a very rare event for a syphilitic parent to transmit the disease to the offspring; and that in the great majority of cases syphilis, the "only serious form of venereal disease," either spontaneously disappears or is readily and permanently cured.

Medical Saints.—The rewards of medicine are few indeed in this world, or even in the next, if we may judge by the small number of practitioners who have been placed upon the calendar of saints. We therefore have cause to rejoice that one more was added to the list by the Pope in the solemn canonization on Ascension Day. The new saint is Dr. Antonio Maria Zacaria, who was born at Cremona in 1503, and studied medicine in the University of Pavia. He practised chiefly among the poor, and died in Cremona in 1563.

The Effect of Civil-Service Examinations.—It is stated that eighteen women who were recently examined under Governor Black's new civil-service scheme have suffered from nervous prostration as a result of the excitement attending the examination. The *Boston Medical and Surgical Journal* thinks that, "if such is to be the general result of the new system, there can be no question that the scheme must be regarded a failure. It is, to say the least, unfortunate that any new source of nervous breakdown, which is not absolutely necessary, should be forced upon our public servants." It would seem rather that a woman whose health is so precarious that it can be broken down by the strain of an examination is not in a physical condition to perform satisfactorily the duties of the place to which she aspires. We sympathize with the ladies who have had this trying experience, but the hard fact remains that the public service is no place for invalids.

The British Association.—The sixty-seventh annual meeting of the British Association for the Advancement of Science began in Toronto on August 18th, and will continue in session till the 25th. About five hundred delegates were registered the first day, and it is thought that the total attendance will be nearly one thousand. On Thursday a reception was given to the members by the Governor-General and Lady Aberdeen in the Parliament buildings.

Dr. L. F. Warner has been appointed special medical examiner for the municipal civil service board of New York.

A Peculiar Accident.—A three-year old child in Newark, N. J., recently picked up something, which is assumed from its effect to have been dynamite, and began to chew on it. Shortly afterward there was a terrific explosion, and the head of the boy was blown from his body and parts of it were hurled for a considerable distance.

Professor Virchow has been elected a foreign associate of the French Académie des Sciences. There are six other foreign associates of the academy, three of whom are Englishmen.

The Sign Language for Deaf-Mutes.—It is proposed to establish in England a college for deaf-mutes, modelled after that established in Washington by Dr. E. M. Gallaudet.

The Coming of the Plague.—According to a newspaper paragraph, which we have been unable to trace to its source, if it has any authentic one, Yersin declares his conviction that the plague which has prevailed in southern China since 1894, and in British India since 1896, is the genuine black death of the Middle Ages, and that it will in all probability reach Europe in a year or two.

Clinical Department.

A CASE OF NEUROTIC ALOPECIA.

By WILLIAM S. GOTTHEIL, M.D.,
NEW YORK,
PROFESSOR OF DERMATOLOGY AT THE NEW YORK SCHOOL OF CLINICAL MEDICINE.

FALLING of the hair may be complete or partial, and either variety may be local or general; and partial local alopecia may not affect the entire area that is diseased, but may occur in circumscribed patches surrounded by an otherwise normal pilous growth. Leaving out of account the cases in which the hair bulbs have been destroyed by inflammatory and ulcerative processes, as by lupus erythematosus or vulgaris, folliculitis, syphilis, etc., as also by the parasitic diseases, ringworm and favus, we may classify the various kinds of alopecia as follows:

1. Congenital alopecia, a rare general form, in which the hair follicles are few in number or absent, and which is usually associated with defects of the nails and teeth.

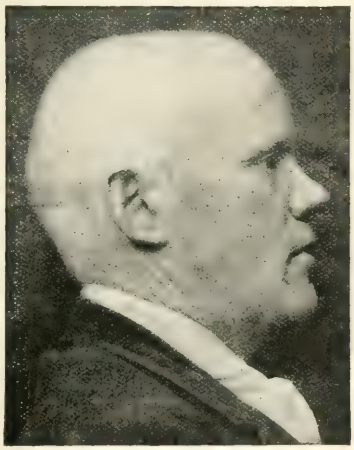
2. Symptomatic alopecia, in which the hair falls out all over the body from constitutional causes. The loss of hair is rarely complete; it is seen after severe illnesses, as after fever following major operations, and in the cachexias, as phthisis, diabetes, syphilis, and leprosy. It is a diffuse thinning of the hair rather than a distinct alopecia, and, while sometimes very extensive, is rarely complete. The prognosis is almost always good; the hair bulbs remain and growth begins again as soon as their nutrition is improved.

3. Alopecia areata, where from a trophoneurotic or a parasitic cause (it is yet undecided which) the hair falls out over localized areas usually circular in shape. The bald spots appear anywhere upon the body, but most commonly upon the head. They may coalesce, and in bad cases almost all the hair of the body falls out, but the history of its appearance in spreading spots is very definite; the skin of each area is completely denuded of hair, but otherwise normal; and at the margins of the coalesced patches a ridge of hair or a few stragglers are usually left.

4. Neurotic alopecia, a rare affection, of which two distinct varieties are to be noted. The partial neurotic alopecia that occurs in the area of distribution of a nerve after an injury of that structure is occasionally seen. General and complete alopecia from neurotic causes is even less common. Cases have been reported by Tyson, Duckworth, Cooper, and others. In almost every case a severe nervous shock preceded the falling of the hair. One case was that of a captain whose ship was struck by lightning; another that of a boy who fell from a great height from a tree. The progress of the alopecia is usually very rapid; in one case it took only ten days; and in some of them the finger and the toe nails were also shed. It is never, however, absolute; a few straggling hairs are left behind. The prognosis in these cases is usually bad; for some reason of which I am unaware the hair does not grow again in its former luxuriance, and sometimes it does not reappear at all. The following is the history of a striking case of the kind which recently appeared at my clinic.

T. Q——, thirty-four years of age, hostler, widower, had never had sickness of any kind save a pneumonia five years ago. As he put it, he had never had occasion to take five cents' worth of salts. He is a man of steady habits, a total abstainer, and he lives with his mother and sister, to whom he is much attached. He has always had a remarkably heavy head of hair and a very thick and bristly moustache and beard; his chest and back were covered with long and tangled hair, so that he was ashamed of himself when he was exposed while bathing; and his arms and legs were equally hirsute. The color of his hair is a vivid red, and, judging by what remains of it, it is of exceptional calibre and stiffness. His history was that at Christmas of last year he lost his job and was out of work for the first time in six years. He worried a good deal about it, since his family was dependent upon him. In February he began to have insomnia and lose his appetite, and he has decreased in weight from one hundred and seventy-four to one hundred and fifty pounds since January 1st of this year. During the last month his hair has been falling out.

When he first presented himself on March 12th of this year his appearance was a striking one. He was



a sturdy, healthy-looking man, somewhat below middle height, with firm muscles, a clear, florid complexion, and seemed fairly well nourished. His head looked "moth eaten," there being a general diffuse falling of the hair over the entire scalp. What hair he had was long, but it came out in bunches at the slightest pull. His eyebrows were represented by about six hairs on each side; the eyelashes were entirely gone. All that remained of his moustache was a few stray but very long red hairs at each angle of the mouth. He had not shaved for a week, and on his cheeks and chin were irregularly scattered hairs, not one-sixth of the normal amount, according to his statement. Chest and back, arms, hands, and legs showed only a few scattered but long red hairs. The axillæ were almost hairless, and on the pubis was a sparse tuft.

He was carefully examined for any signs of syphilis, past or present, as well as regarding the presence of any disease of the internal organs, but no sign of anything of the kind was discovered; and the only conclusion that it was possible to come to was that the case was one of true neurotic alopecia caused by mental anxiety. The treatment consisted of general tonics, arsenic with nux, and the mineral acids, together with the local use of a bichloride and adeps lanæ ointment (1–1,000) for the scalp.

During the two months that he was under treatment the alopecia steadily progressed. A few scattered hairs only remain on the scalp and face; the moustache and eyebrows are entirely gone, and the body is quite free from hair save a few stray ones upon the pubis. He has slept and eaten better, and is not so worried; but the falling of the hair continues.

As I mentioned above, the prognosis as to a renewed growth of the hair is not good. Why this should be

so it is hard to imagine, for the depressed state of nutrition which the skin shares with the other organs of the body in conditions such as his can hardly be severe or prolonged enough to lead to a permanent atrophy of the hair bulbs. It is possible that some good may be gotten by the systematic use of the faradic brush, or from chrysarobin, or from the hypodermatic injection of small doses of pilocarpine. But the records of these cases usually show a result that is very unsatisfactory.

HYSTERECTOMY.[1]

By E. T. KINGSLEY, M.D.,

[illegible], TEXAS.

When an operation becomes so common and has been given so much careful thought as hysterectomy, it ceases to have that interest to the average physician that it did as an innovation in surgery, unless there should attach to the case some unusual history—something of uncommon interest in the operation or its results. Believing that I have a few such cases, I am prompted to place on record the following:

Case I.—Miss K——, aged eighteen, aborted September 3, 1894, between third and fourth months, two or three weeks after the criminal induction thereof. I saw her first on September 9th, and found her with a temperature of 105° F., pulse quick and full, and great pain and tenderness over the lower abdomen. She was curetted, washed, and packed twice in the next week, with the effect to cause a slight reduction in fever. These symptoms continued without incident until September 29th, when an abdominal section was made. Extensive adhesions were found in and around both tubes. The ovary and tube on the left side were successfully removed, but the one on the right contained an abscess, partly within the wall of the uterus and partly in the tube, the walls of which would not hold a ligature; cutting through left a large hole in the uterus through which pus ran freely. The womb was large and soft, and infiltrated with pus. This predicament left us no alternative but hysterectomy, which was accomplished without trouble, and the patient made a prompt and complete recovery, and is now able to ride a bicycle and work as before, and looks better. This operation was done at the patient's home, amid very unsafe surroundings.

Case II.—Mrs. G——, aged thirty-nine, was brought to my private hospital, January 14, 1895, from an adjoining town. She was the most perfect picture of a living skeleton I think I ever saw; her pulse was barely perceptible and very irregular, and she had occasional attacks of dyspnœa. I learned that she had come to Texas from Missouri four years before for lung trouble, having had repeated hemorrhages. She had had only one in Texas. Physical examination of her chest revealed a dry cavity in the apex of the right lung. She had been confined on November 2, 1894, with her tenth child, and the confinement was followed by fever which continued till I saw her. Eight years previously she had been confined to her bed three months following a confinement, from which she dated her pelvic trouble. I found a deep bilateral laceration of the cervix, and it was filled with polypoid growths. There was a copious muco-purulent discharge, great tenderness in the vault, especially to the left, and the womb was fixed. There was a large tumor on the left side, the outlines of which could be distinctly seen extending from the pubis to nearly the border of the ribs, and it was exquisitely tender. After five days' meditation, an operation was decided upon. The abdomen was opened on January 19th. The appendages were found free on the right side and removed, the uterine artery was tied, an opening made into the vagina in front and behind, and the reverse course pursued on the left side, according to the method suggested by Prof. Howard Kelly. On the left the womb was tied off from below upward, and the adherent and suppurating masses, from which streamed quantities of pus, were left intact, after being washed carefully with hot decinormal salt solution, and the surface and interstices so far as possible covered with iodoform gauze projecting into the vagina and out of the abdominal wound. She began to improve at once, and soon the attacks of dyspnœa, which occurred several times daily and for which digitalis and large doses of strychnine were given, became less; her convalescence was rapid, and six months later she paid me a visit on her way North, the picture of health. At last accounts she was well.

Case III.—Mrs. Y——, aged forty-one, has one child, a boy aged fourteen; labor was prolonged and instrumental, and since then she has had headaches increasingly violent, for which finally she travelled and was treated more or less constantly. Some eight or ten years after her confinement a deep bilateral laceration of the cervix was discovered and repaired, giving her temporary relief. A few months after this operation she had a pelvic inflammation, which resulted in a pelvic abscess, which was opened in the posterior cul-de-sac. This abscess cavity and sinus refused to heal, and she was treated at home and in the Woman's Hospital, New York, and elsewhere a year before it closed; her headaches continued to increase, although she no longer suffered from any pelvic trouble that she was conscious of. She became finally a complete invalid by reason of these headaches, was confined to her room and bed most of the time, and was compelled to use morphine, whiskey, and other drugs more or less constantly to get any relief. She finally came under my systematic care. In January, 1895, I found the womb perfectly fixed and some tenderness on deep pressure; she was a short, thick-set woman, with thick tense abdominal walls. This was all I could make out, but this was enough to establish the fact to my mind that this was a probable cause of her reflex pains. Careful examination enabled me to exclude other organs, except possibly the brain. I did not, therefore, hesitate to advance the opinion that the headaches were of pelvic origin, and that nothing short of a hysterectomy would relieve them. In order to be more certain of my ground, I obtained the opinion of several of the ablest gynæcologists in the country, all of whom except two agreed with me. Accordingly, on March 25th, the abdomen was opened; the right tube and ovary were dug up—if I may use this expression—with great difficulty and removed. The tube was at least one inch in diameter, and filled with pus; the left but little smaller, but containing no pus. This also was removed, and the womb, not very much enlarged but very hard, followed. Time, two and one-half hours. From the moment she became conscious after the operation she said her headaches were gone, and for two weeks until she was nearly ready to sit up she never ceased to wonder at her great relief. At this time the nurse heard her moaning in the night, and upon going to her found her right side paralyzed; she was completely aphasic, but could understand what was said to her. In the course of twelve hours she became unconscious, and the paralysis, both motor and sensory, was complete; there was partial ptosis of the left eyelid, and an ophthalmic examination showed the disc in the left eye somewhat cloudy. It was determined to open the skull on the left side, which was done by Dr. Robert

[1] Read before the gynæcological section of the Texas State Medical Association, at Paras, Tex., April 27, 1897.

E. Moss. There was no pulsation of the dura, which was incised, nor was anything discovered to account for her condition. The wound was closed, with the confession that we were baffled. She died on April 19th, one week after the last operation and over three weeks after the hysterectomy. An autopsy revealed a perfect condition in the pelvis; the vaginal vault was closed as perfectly and smoothly as though there had never been any womb there; the intestine lying over it was attached by a small segment. On removing the skull cap a diffuse blood clot was seen covering the entire right hemisphere, quite thick and dense, posteriorly. There was no necessity for searching farther for an explanation of the situation. The arachnoid was adherent at two or three small points along the border of the great longitudinal sinus. It is interesting to speculate on what connection if any the first operation had to the cerebral hemorrhage; second, that the hemorrhage was on the side of the paralysis, which rather goes to disprove some of our theories of cerebral localization.

Case IV.—Miss R——, aged twenty, had suffered from dysmenorrhœa for several months, the excessive flow lasting for weeks, but there was never any pain except near the menstrual period. For this condition she was in the course of three years curetted and packed several times, which checked the hemorrhage only for the time. In the latter part of April, 1896, a distinct tumor was discovered on the left side, which had made its appearance and grown rapidly long after she had had any treatment. She was now having a light fever continuously, was profoundly anæmic and very weak. An operation was advised and done, May 2, 1896. The right tube and ovary were free and normal in size and appearance, but wedged against the pelvic wall by pressure of the tumor from the opposite side; on the left was a tumor filling the pelvic and abdominal cavities, and extending nearly to the border of the ribs, to which the intestines were adherent. The tumor was so dense and vascular as to remind one of a soft myoma, which I thought it was until the womb was removed. I found it impossible to free the tumor from its bed from above; so I removed the adnexa on the right, divided the broad ligament between sutures, opened the vault before and behind and as on two or three former occasions reversed the order, working from below upward on the left. When I came to the tube its wall ruptured, letting a few drops of pus escape. It was now for the first time that the true nature of the tumor became apparent; the rent was seized with forceps to prevent further escape of pus, and the tumor dissected out carefully *en masse*. Great care was necessary to avoid the ureter, as the mass lay over its entire course. An iodoform gauze tampon was used for drainage, and the abdominal wound was closed. Examination of the tumor showed its walls to be about one-fourth of an inch thick and very vascular externally. Some five days after the operation a copious watery discharge from the vagina began. This kept up until the middle of September, with only an interval of two or three days. The amount of the discharge was enormous; it was neutral in reaction, with a specific gravity of 1.005, and odorless until after standing a number of hours, when a slight urinous odor developed. The quantity of urine passed from the bladder was normal in quantity and quality. About the middle of September it ceased altogether, and thereafter for three or four months violent paroxysms of pain over the right kidney occurred at about the regular menstrual periods, accompanied by fever and purulent urine. This condition was remedied by the administration of morphine, salol, and hyoscyamus. For the last five months she has been entirely free from any trouble, steadily gaining in color, flesh, and strength, and is now feeling better than for several years. Interesting points in this case were the freedom from pain throughout the sickness before and after the operation, except at the menstrual period, and the fact that there was no vaginal or abdominal tenderness; the rapid development of an enormous pyosalpinx; the copious vaginal discharge continuing for months, which could come only from a wounded ureter, and its final spontaneous closure.

From a study of these cases the following conclusions seem to be justified: First, in pus cases we may find the womb normal and the pus confined to one side, the other remaining also normal, or we may have both tubes and womb completely septic; and we must therefore not enter the abdomen with a preconceived determination to do a certain operation, but with a view of doing what circumstances demand. If we have a young woman or married woman without children, it may be advisable to undertake to save one tube and ovary if possible, even at the expense of a second operation later. Second, in all pus cases we are bound to have displacement and adhesions, and the tissues involved are irreparably damaged. Hence it is absurd to do these operations per vaginam, because the womb is fixed and the relations of the parts are changed, necessitating blind surgery and leaving behind diseased tissues certain to give rise to future trouble. Third, strange and incomprehensible reflex complications often accompany and follow pelvic disease. Fourth, in cases of sepsis following abortion or occurring in the puerperium, the safest time to operate is after a few weeks rather than immediately. I wish to acknowledge the great assistance given me in these cases by Drs. F. Paschal, F. M. Hicks, R. E. Moss, and my sister, Dr. Josephine Kingsley.

A MALINGERER (?).

By EDGAR J. SPRATLING, M.D.,

Second Assistant Physician, Matteawan State Hospital, Matteawan, N. Y.

In the winter of 1891–92 a beggar who pretended to be horribly deformed with rheumatism was refused alms by a rabbi who had been warned against him as a fraud; for this refusal the beggar shot him. A conviction followed; in prison he would obey no orders, was filthy, noisy, and violent. He was given the benefit of any doubt that might exist and committed to the hospital for insane criminals. There he at once began to find fault with everything, and declared that he was beaten, poisoned, and in many ways persecuted, none of which complaints were based on fact. He soon began to break furniture, yell, and make assaults on those about him. For these acts, frequently repeated, he was placed in a separate room with screened windows, whereupon he pretended to become physically insensible and paraplegic, could not or would not take food or control the sphincters. He was then fed by means of a tube and received an infant's care. This condition lasted during the two following years, examinations being made from time to time, each apparently giving akinesia and analgesia of the lower half of the body. He resisted every examination and for a day or two afterward would pour out a stream of complaints in a whining tone, of heat, cold, bad odors, repulsive sights, annoying sounds, etc., all of which were baseless materially. At times he would show blood on his bedding, declaring that he had had a pulmonary hemorrhage, but under guarded observation it was found to come from self-inflicted injuries of the gums; and one night while under observation he was seen to climb up the window to get and eat a piece of cheese put there by another patient. The next day in spite of his resistance a Sayre's apparatus and a fara-

dic current were used. A few days of this treatment and he began to walk, though in a halting manner, and the sphincter paralysis disappeared, but he would immediately relapse into his former state of pseudo-paralysis whenever the apparatus and battery were taken from the ward. He was kept up and made to go to the dining-room and exercise court, much against his will, till February, 1897, when he passed a small amount of blood by the rectum. Examination simply confirmed many previous ones, giving an enlarged spleen and small liver, but no reason for a sudden collapse and resumption of the old state in all its details. But two days later anasarca of the feet and scrotum was noticed, followed rapidly by ascites. After only five days tapping gave nearly two gallons of fluid, and on every second or third day thereafter a like amount was withdrawn. He generally appeared insensible or pleaded paralysis, but at rare intervals would walk about the ward at will.

In May he died. The post-mortem gave old excoriations of the leg centres and two inches backward on both hemispheres. No other pathological or developmental peculiarity of the brain or nerves could be found. Liver hobnailed and about one-third size; spleen about four times increased; heart, lungs, kidneys, and intestines normal.

The patient was syphilitic. Absolutely nothing of his past could be learned, but he was supposed to have been born an Algerian Mohammedan and to have led a haphazard existence from childhood. The probabilities are that he had had syphilitic paralysis at some time in the past and that locomotion was difficult and painful and his delusions and hallucinations were genuine, but that all mental and nervous troubles were many times multiplied for a malingering purpose. This belief is strengthened by the fact that he never did complain of the real physical disease of which he died—cirrhosis of the liver.

Stated Meeting, June 21, 1897.

JOSEPH E. JANVRIN, M.D., PRESIDENT, IN THE CHAIR.

The Biparietal Diameter as a Symptom and Diagnostic Criterion of Tuberculosis.—DR. MARK I. KNAPP read the paper (see page 265).

In discussing Dr. Knapp's paper DR. C. E. QUIMBY said this seemed a new line of research. The author might well have discussed the narrowness of the biparietal diameter in those who did not have tuberculosis, for it would be interesting to know if non-tuberculous individuals had wide biparietal diameters. If the narrow biparietal existed in other than tuberculous patients, how could the argument that the two were due to the same cause be deduced? The line of investigation might be an interesting one, but he still felt that he would prefer to rely upon the methods now followed, viz., physical examination of the patient, with the evidences found by inspection, palpation, percussion, and auscultation, than to rely upon the mere fact that the individual had a narrow biparietal diameter. It was evidently more beneficial to the practitioner and doubtless more satisfactory to the patient.

DR. KNAPP said the diameter varied in different individuals, but the whole head had to be taken into consideration and the fact of a wide or narrow biparietal diameter be determined by comparison with other diameters. He had a theory as to certain anatomical abnormalities in connection with other diseases, which he hoped to be able to present at some future time.

The Genital Phenomena of Renal Calculi.—DR. R. ABRAHAMS read the paper upon this subject. He proceeded to give the history of several cases in which the genital phenomena were the only indications of the existence of the affection and the approach of its most painful manifestations, colic.

The first case was that of a man, single, aged twenty-two, healthy. He was seized with pain in the right testicle and taken home bordering on collapse. He vomited once or twice during the evening and had nausea in the intervals. The abdomen was normal; the right testicle was very tender and the seat of excruciating pain, accompanied by swelling and tumefaction. The epididymis was hard and painful. The urine gave no aid to diagnosis. There was no history of gonorrhœa, but the affection was diagnosed as acute epididymitis of gonorrhœal origin, which was distasteful to the young man, as he was on the eve of matrimony. The treatment was such as is usual in epididymitis. After four days' attack of violent pain in the region of the right kidney, radiating down the pelvis and thigh, the patient passed a large quantity of urine mixed with blood, gravel, and large and small fragments of broken calculi. Simultaneously with the discharge of débris the testicle began to improve and two days later the patient was out of bed, hale and hearty, the pain and swelling gone.

The second case was that of a man and was similar to the first. The third case cited was that of a woman, married, aged thirty-three, who was healthy until December, 1895. Her physician said she then had an attack of acute ovaritis. This attack kept her in bed a week, with ice on the pelvis and morphine suppositories in the rectum. The recovery was complete. Just a year later she had a similar attack. In the absence of the family physician the writer was called. She had frequent vomiting, coated tongue, was constipated; pulse feeble and rapid; temperature, 101° F.; extremities cold; face pale and covered with sweat. The left ovary was enlarged and exquisitely tender. At the end of a week, after a large warm injection, the woman passed a good quantity of water mixed with gravel and particles of broken calculi. Relief in the ovarian region was immediate, and a few days later the previously enlarged and tender ovary could hardly be felt.

The writer would not have any one infer that every instance of sudden onset of pain and swelling of the testicle or ovary attended by no history of sepsis or traumatism was a *bona-fide* expression of stone in the kidney, yet he would beg every one to remember the possibility of the occurrence of such a state of things. The literature dealing with the possibility of such a cause in ovarian troubles was very scanty. There was more literature on the subject of the affection of the testicle in cases of renal calculi. Dr. Abrahams also cited the case of a boy two years old, in which orchitis was due to a stone. The child had several attacks, each one leaving the testicle more tender, until it had to be supported and was sensitive all the time. On one occasion the child was brought with the history of retention of urine. The bladder was distended, the testicle swollen and tender, and the penis somewhat œdematous. A stone was found embedded in the bulbous portion of the urethra, and after its removal the child was at once relieved and has had no attack of orchitis since, now two years. The significance of the genital phenomena as indicating renal calculi, if rightly interpreted, might be of great aid in preventing an attack of renal colic.

In discussing Dr. Abrahams' paper, DR. ROBERT NEWMAN said one would think it easy to diagnose renal calculi, but at the bedside it was not so easy.

The writer had given a valuable point, but even that would not remove all the difficulties. There were to be considered the many affections to which the genital organs were liable, as orchitis, etc. Then gout, pyelitis, etc., often made the diagnosis of renal calculi difficult. Catheterization of the ureter aided somewhat, but even that did not always settle the matter. He cited a case in which the patient had a large renal calculus necessitating removal of the kidney. The patient recovered, but the next year she had a large calculus in the remaining kidney. Dr. Campbell succeeded in removing this from the kidney and the patient recovered.

Dr. Thomas Manley said the purpose of the paper was in the right direction, as it treated of symptoms, and symptoms led to diagnosis. He thought there was not much difficulty at the present time in diagnosing renal calculi, and if the urine were examined it would be likely to reveal the difficulty. He had not met any cases similar to the ones referred to by the writer of the paper.

Dr. L. B. Bangs said he had not hitherto had his attention called to the subject as presented by the writer, and he thought the suggestions were quite interesting. Renal calculi did not prove so very difficult of diagnosis, but the suggestions made might be of importance. He recalled a hospital case in which the patient had what was supposed to be tuberculosis of the testicle, but after a time he passed a stone and the case cleared up.

Drs. McCleod, White, and Newman were appointed a committee to arrange for appropriate exercises at the next meeting of the association, in memory of Drs. Smith and Lusk.

A motion to appoint a committee to revise the by-laws and constitution was carried.

THE NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, February 24, 1897.

John Slade Ely, M.D., President.

Total Thrombosis of the Left Pulmonary Artery.—Dr. James Ewing presented a specimen which had been taken from a woman, thirty-eight years of age, a laundress by occupation. The previous history was negative except that there was an absence of rheumatism. She had not been very ill until about six months before her death, which had occurred on February 18, 1897. On her admission to the hospital there were the physical signs of advanced mitral stenosis. During the two or three months she was in the hospital, the course of the disease was that of a severe mitral stenosis. The principal symptoms were referable to the pulse, which was irregular, small, and at times very intermittent. At one time there was a very severe attack of tachycardia in which the pulse ran up to 180. There was one attack of severe hæmatemesis. The pain in the precordium was severe throughout the illness, but there was no history of an acute exacerbation of this symptom. There was considerable œdema at the time of admission, and this increased steadily up to the time of her death. The urine contained albumin and numerous casts. The manner of death was of interest. She became delirious about five days before death, but at no time showed any severe acute exacerbation of the symptoms, such as would indicate the occurrence of the thrombus or an occlusion by an embolus. She was comatose for two days before death. There was practically no fever during her stay in the hospital. During the last two weeks the temperature did not rise above 99° F., and there were no evidences of pneumonia. At the autopsy it was noted that there were moderate anasarca and jaundice, and on opening the thoracic cavity the right lung was found to be consolidated. There was about one litre of slightly blood-stained serum in the left pleural cavity. The left lung appeared to be somewhat diminished in size. It was apparently the seat of the ordinary consolidation that occurs in advanced heart disease, but on section the lung was found to represent a complete infarct, the whole tissue being studded with rather large infarcts. The pleural surfaces of the lower lobe had become adherent, and when torn apart showed a large cavity in the lower lobe which had evidently arisen from softening of an infarct. In the upper lobes were two areas of softening. Around all the infarcts were areas of lighter color, representing the zones of hyperæmia. The other lung showed two infarcts. The heart was of moderate size, and presented a uniformly narrowed mitral valve, admitting the tip of the little finger. All the chambers of the heart were dilated. There was hypertrophy of the left auricle only. The left auricular appendix contained an old and partly organized thrombus. There was some freshly clotted blood in the right side of the heart, but there were no old parietal thrombi or points of origin here for a thrombus. The liver showed advanced chronic congestion, and the kidneys chronic congestion with nephritis. The spleen was much enlarged and congested. It was evident from an examination of the specimen that the lung had been converted into a single large infarct. The large cavity in the lower lobe was surrounded by fibrin where it had been adherent to the parietal pleura, and evidently antedated the one in the upper lobe. It was interesting that no date could be fixed for the beginning of this extensive lesion, and that, notwithstanding its existence, the patient was able to breathe fairly well. This history was in marked contrast to that of the case in which sudden death occurred after confinement, being caused by the occlusion of one branch of the pulmonary artery by a thrombus.

From a pathological standpoint the etiology was also of interest. It might be supposed that the lung had first been the seat of a pneumonia, and afterward of a thrombosis which finally reached the pulmonary artery. On section, however, aside from the lesions of chronic congestion, there was no inflammatory exudate found except in the zones around the infarctions; hence such an origin could be excluded. Another possible origin was an endarteritis of the pulmonary vessels leading to a parietal thrombus, beginning perhaps in the lower lobe and causing the gangrenous cavity; but on section none of the lesions of endarteritis was found. A third possible mode of origin was the ordinary marantic thrombus, but one would naturally look for some other exciting cause, as, for instance, a small area of inspiration pneumonia leading to thrombosis of a vessel which, owing to the failing circulation, had increased until the entire pulmonary artery had been occluded. None of these explanations seemed to the speaker entirely satisfactory. It was worthy of note that the thrombosis could not have arisen from the heart, as there was nothing in the right side of the heart to give color to such a view.

Hæmato-Myelopore—A New Spinal-Cord Disease.—Dr. Ira Van Gieson said that since 1886 he had been engaged in a study of the origin, nature, and distribution of certain slender columns or canals in the spinal cord, which had been hitherto unexplained. He believed they were expressive of a disease of the spinal cord of a distinctive individuality, deserving a special name, and he had therefore given to it the name "hæmato-myelopore." The word is from the Greek, and signifies an aqueduct or canal in the spinal cord arising from a hemorrhage.

The speaker said that he had first met with this lesion of the spinal cord in 1886 at the St. Catharine's Hospital in Brooklyn. The patient was a middle-aged man who, in falling from an ice wagon, had injured his back. He developed a severe paraplegia, but lived for nine months. The autopsy showed an old fracture of the spinal cord at about the twelfth dorsal segment. The spinal cord at this point was reduced to a small band. Extending upward through the whole dorsal region was a narrow, slender, partly tubular canal, which contained necrotic elements of the cord substance. Dr. Van Gieson here exhibited drawings of the lesion found in this case. He said at the time the condition had been mistaken for syringomyelia. The specimens were taken to the pathological laboratory at Heidelberg, where the opinion was also expressed that the case was one of syringomyelia. Some time afterward Dr. Dana had secured an autopsy on a woman who had been suddenly seized with an acute transverse myelitis, occurring without traumatism. This case also showed a long narrow tubular canal in the spinal cord. The focus of the myelitis was found in the mid-dorsal region. Dr. Dana published the case in 1889 under the title "A Case of Acute Myelitis with Central Perforating Necrosis of the Spinal Cord." In 1891 the speaker published the case first referred to under the title "Traumatic Myelitis; Destruction of the Twelfth Dorsal Segment, with a Column of Necrosis Extending into the Dorsal Region." More recently he had met with three or four cases of traumatic hæmatomyelia. The mechanics of the spinal cord showed why it was necessary for blood escaping into the cord to assume the form of slender columns. The distribution and topography of these hemorrhages so closely simulated that of the canals already referred to that he was led to look upon these hemorrhages as the true explanation of the "perforating necrosis." Blood passes through the gray matter and disintegrates it. After a time this may be absorbed, leaving a clean-cut hole in the spinal cord. Up to the last few months he had been unable to find the intermediate stage between the columns of hemorrhage and the perforating necrosis, but through the courtesy of Dr. Fraenkel he had been able to study a case in which this intermediate stage was present. There is a disposition after a time to the formation of new neuroglia tissues about these long slender canals, and it was for this reason that the condition had been mistaken for syringomyelia. The symptoms of hæmato-myelopore are entirely distinct from those of syringomyelia, although resembling them in some particulars. The structural resemblance between the two diseases is due to the inflammation which tries to replace the tubular gap in the spinal cord in hæmato-myelopore. Dr. Van Gieson said that he had artificially injected the spinal cord with colored gelatin, and had found that these injections took the form of the columns observed as a result of hemorrhage.

Dr. Ewing said that the society should be congratulated on being the first to hear the presentation of this important subject. The speaker had stated that the course of the blood was determined by the limitation afforded by the pia mater. It would seem to him that the blood should be able to travel in any direction within the limits of the pia mater; hence he could not understand this slender columnar distribution. The charts exhibited would seem to indicate that near the source of the hemorrhage several such columns were sometimes present.

Dr. Van Gieson replied that if the spinal cord were injected with colored fluids it would be found that more resistance was met with in passing transversely than in passing vertically through the cord. The two crescents of gray matter are softer and more spongy than the nerve fibres, and hence offer less resistance. There are interstices between the nerve fibres which constitute slender canals—indeed, the whole spinal cord would appear to be constructed as if it were itself a columnar or tubular formation.

Dr. Van Gieson then announced the publication of a more detailed presentation of the subject in the State Hospital's Bulletin and a final presentation of the disease for the congress at Moscow during the coming summer.

Surgical Meeting, March 10, 1897.

John Slade Ely, M.D., President.

The Results of Experimental Nephrectomy in Dogs as Bearing upon the Uræmic State.—Dr. C. A. Herter presented a report on the results of his study of this subject, chiefly with a view to indicating that the blood, after ligation of the vessels, or removal of the kidney, underwent a change in its toxicity. The paper was based on fourteen observations, all of which were upon the dog, with one exception. In that case the pig was the animal experimented upon. In one animal death followed the removal of one kidney, and this was explained by the fact that after death the other kidney was found to be the seat of an extensive hydronephrosis. Both kidneys were extirpated in six dogs, and in the pig. The average duration of life was two and a half days, the shortest being twenty-four hours, and the longest four and a half days. Immediately after the operation, there is usually considerable prostration; in the case of the pig there was, however, marked restlessness. The first striking symptom is vomiting, which usually begins about the end of the first twenty-four hours. It is usually repeated a number of times and then ceases. The vomited matter is ordinarily bile stained, and sometimes contains blood. In four of the dogs diarrhœa was associated with the vomiting, more or less blood being commonly present in the diarrhœal discharges. Food was refused by all the animals except the pig. At the time of the vomiting there was usually much prostration, and the respirations became much slower and deeper, being reduced from 50–80 a minute, to 25 a minute at the end of forty-eight hours. In some instances, the rate fell as low as 14 to the minute. At first the heart action was normal, but it usually became slower after a while, the reduction being from 150 to 80 a minute. This was associated with a distinct increase in the force of the heart's action, and usually in the fulness and tension of the pulse. After forty-eight hours the nephrectomized animal was apt to become drowsy and remain in this state until death. In some of the dogs, living more than fifty hours, there was fibrillary twitching of the muscles. In only one case was there a true convulsive seizure. This occurred in a dog living eighty-two hours after the removal of both kidneys. It was preceded by pronounced fibrillary contractions, and consisted of clonic spasms of several minutes' duration. It terminated fatally. Such seizures, the speaker said, appeared to be quite rare in cases of experimental uræmia. He had not been able to satisfy himself that blindness ever occurred in these dogs. During the last hours of life the respirations were even slower than during the middle period, but they were more shallow. In some instances there was pronounced irregularity of breathing, sometimes suggestive of Cheyne-Stokes respiration. These symptoms justified the belief that they were dependent upon paralysis of the respiratory mechanism. Death, however, invariably occurred from respiratory failure. On the other hand, the heart, even in the terminal stage, continued to act forcibly, and maintained a nearly normal arterial pressure to the end. On division of the vagus nerves at this time, the pulse rate was increased.

The cardiac symptoms were evidently the result, in part at least, of vagus inhibition. In several nephrectomized dogs there was a striking increase in the fulness and tension of the femoral pulse, in comparison with that found before operation. No doubt such a pulse in a nephritic patient would be called a high-tension pulse. At times, the heart sounds were much increased in intensity on the second or third day after nephrectomy, and the aortic second sound was especially loud and valvular. In these animals the temperature was never increased above the normal, except as a result of sepsis; on the contrary, the temperature was one to three degrees Fahrenheit below the normal for the greater part of the period of observation. The symptoms were practically the same in all the animals, whether the kidneys were removed or the ureters were simply tied—a matter of much importance, as it showed that Brown-Séquard's theory of uræmia was hardly sustained.

A most important feature of these cases was that the blood serum was found to be increased in toxicity if taken twenty-four hours or more after operation. The degree was roughly related to the duration of the experiment. This toxicity was either much reduced, or quite lost, by exposing the serum for a few minutes to a temperature between 60° and 67° C. The change in toxicity was associated with a darkening of the serum and the development of a peculiar odor. Dr. Herter said that he had not yet been able to determine the point at which this change in toxicity first took place. It was sometimes noticeable that this loss of toxicity was not so complete with an exposure for two minutes to a temperature of 67° C. as with an exposure of five minutes. At times there was a slight separation of a reddish gelatinous material at this temperature, but without distinct coagulation. It was possible that the substance whose activity was destroyed was a globulin, but all attempts to determine its nature had hitherto failed. It was important to note that the normal serum of the dog was toxic to rabbits. Former observers, the speaker said, had not noted that in the case of dogs the normal serum underwent a striking reduction in its toxicity when it was heated in the manner just described in connection with the foregoing experiments. The increase in the toxicity of the serum varied: sometimes it was not more than one-third more toxic than the normal serum, but in other cases it was from two to six times more toxic than the normal.

It was important to emphasize the fact that the results obtained by this experimental study were of the most definite character, and that the results had been concordant in all the cases in which the serum of nephrectomized animals had been tested. In these experimental studies the rate of making the injection was of importance. For instance, if made too rapidly, more serum would be injected than was required to cause the symptoms or produce death. He had found that the rate should be from two to five cubic centimetres per minute. It was important to distinguish between the results obtained in studying the toxicity of urine and those from a study of the toxicity of the blood serum. In the case of the urine, the potassium salts form an exceedingly important element, as from sixty to eighty per cent. of the toxicity of the urine is due to the presence of these salts—in other words, only a comparatively small proportion was due to the organic ingredients, such as urea, extractives, etc. Unless, therefore, we knew just how much potassium salts were present, particularly the chloride, we could not say just how much of the toxicity was due to the salts. In the blood serum there would be found very little potassium salts. The diminution in toxicity in the experiments could not be ascribed to the destruction of the extractives and urea, because a far higher temperature was necessary for their destruction. The diminution of toxicity appeared to be due to a substance similar in its properties to that found in the urine of some cases of human uræmia. In both cases, the toxicity was destroyed or reduced by the application of heat, and the color and odor underwent similar, if not identical, changes.

The muscles and the liver were extracted with a two-per-cent. salt solution at the room temperature, and the clear extracts were injected into rabbits. It was found in this way that the liver did not store the thermo-sensitive substance, and that it did not give positive toxic results. We must look to the skeletal muscles for information regarding the thermo-sensitive substance which was responsible for the change in the toxicity of the blood. Occasionally, massage had been found harmful in patients with chronic nephritis on the verge of uræmia, resulting sometimes in aggravating the dyspnœa and general discomfort. An extract of the muscles of the normal dog when injected into rabbits was found also to be toxic, but in a rather different way, the animals dying apparently of suffocation and without the development of convulsions. The significance of this observation was not yet known. As was well known, the urea of the blood in the nephrectomized dogs was increased from two to ten times the normal amount, varying with the time the animal lived after the nephrectomy. In the nephrectomized dogs, changes in the color of the retina had been observed. Marked congestion of the intestine was quite frequently found in these animals. A marked congestion of the mucous membrane of the small intestine, of uneven distribution, was commonly found after forty-eight hours. The mucous membrane of the stomach was often moderately congested, as was also that of the lower colon and rectum. A similar congestion might be produced by large intravenous injections of urea, but the congestion was apparently not due to urea in the experiments under consideration, as comparatively small quantities of urea were found in the intestine. A similar congestion was produced by injecting into dogs the serum from uræmic patients.

Dr. Herter said that he had analyzed forty-one apparently reliable cases in which anuria in the human subject had lasted more than four days. Of the twenty one autopsies in these cases, the ureter or pelvis was obstructed by calculus in fourteen, and in three growths obstructed the ureters. Of thirty-six cases in which there was absolute or nearly total anuria, in eleven the anuria lasted more than four days, and in seven more than fourteen days. In seven of the forty-one cases no uræmic sypmtoms occurred, although the duration of the anuria was from five to eleven days, and caused death in at least three of the cases. In a number of the cases more than a week elapsed before the indications of uræmia began; in most cases it was from the seventh to the ninth day. In twelve of the forty cases, vomiting was present at some period. Diarrhœa was noted in only six cases. Insomnia and restlessness were observed early in a number of the cases. Pronounced delirium and general convulsions were rare. Muscular twitchings were observed in about one-fourth of the cases. The mental faculties were often but little impaired. Death was usually preceded by drowsiness, if death were deferred more than a week. Motor paralysis was not noted in one of the forty-one cases. In four cases there was a urinous odor in the breath. Contraction of the pupils was a common and characteristic symptom. The temperature was elevated in only one of these cases. In the last days of life the temperature was apt to be subnormal. On comparing the symptoms of human obstructive and experimental obstructive uræmia, it would be found that vomiting was an early sympotm: that marked muscular prostration was usually present in both: that delirium and paralysis were absent in both: and that in the

terminal stage fibrillary twitchings were common in both and general convulsions were exceptional. The most important clinical resemblance was that the temperature was normal or slightly subnormal. A patient with both ureters blocked might live two weeks, yet a dog with both ureters tied did not live more than one week. This difference could hardly be ascribed to the shock of the operation. The pupils were much more apt to be contracted in man than in dogs. When the urea in the blood of a dog accumulated beyond a certain point (five per cent.), it was excreted by the intestine. It would seem probable that the pathological conditions in nephrectomized dogs were essentially those which were responsible for the symptoms of obstructive uræmia in human beings. Unfortunately we had no definite knowledge of the condition of the blo o in cases of obstructive uræmia in the human subject. It should be remembered that uræmia was not a specific intoxication, but is due to the accumulation of several classes of toxic substances in the blood when the kidneys were unable to do their work properly.

Dr. James Ewing asked if in the liver of the dog any condition resembling that found in cases of eclampsia had been observed—in other words, was there any indication of a hemorrhagic hepatitis?

Dr. Herter replied that he had observed this condition of the liver in some cases of puerperal eclampsia and a somewhat similar condition in some of these dogs, but he did not feel sure that the two conditions were identical.

Dr. Ira Van Gieson expressed his high appreciation of work of the class represented by this paper. He said that he had induced uræmia in some animals by injecting the serum from uræmic patients, but his observations had been too few to be of much value at the present time. He predicted that bleeding would come into favor again as a therapeuic measure, simply because of its removing toxic substances from the blood. The examination of the cells of the cerebellum in three uræmic cases that he had studied showed, in slight degree, the mark of toxic degeneration—a resolution of the cytoplasmic elements of the cell. Four rabbits were injected with the serum of uræmic cases, in small amounts and cumulatively. He preferred to introduce a time element rather than to give the serum continuously up to a fatal result; he preferred to have from six to forty-eight hours elapse before death, as this offered a better standard of comparison. The animals showed an œdema of the upper extremities and died with œdema of the lungs. The pleural cavities contained over an ounce of transuded material—a condition that he had never seen in any other experiments on rabbits. The temperature dropped from 103° to 99° F., and remained so for some time after the injection. An increase of temperature in a rabbit was very easily produced, but a decrease in the temperature was a matter of much greater significance.

Dr. Herter, in closing, said that he was inclined to agree with the last speaker regarding the time element in these experiments. It probably enabled one to detect with accuracy smaller differences of toxicity, but by the method that he had employed the differences had been sufficiently striking to lead him to continue it in order that he might make fair comparisons with the earlier case. He was very strongly disposed to accept the statement that bleeding would become in the future a much more frequent therapeutic measure, yet it should be remembered that these conditions were often very complex. The most favorable conditions for bleeding were: a good heart action and a high-tension pulse, moderate anæmia only, and intense dyspnœa. The relief to the dyspnœa was most striking, even when the administration of arterial dilators gave little or only very temporary relief.

Aortic Valve with Only Two Segments; Adult Heart; Congenital Origin.—Dr. E. P. Shelby, Jr., presented a specimen that had been removed from a man, forty years of age, admitted to Bellevue Hospital on December 12, 1896. He gave a history of having suffered since infancy from shortness of breath and nervousness. He did not remember having had rheumatism or chorea, or any of the infectious diseases of childhood. The only serious illness that he had ever had was an attack of pneumonia, which had occurred in his twenty-fifth year. He had been a steady drinker of whiskey and had used tobacco to excess. He had never had any venereal disease. Two weeks before coming to the hospital he had caught cold and had become feverish, had felt a soreness in the chest, and had begun to cough. After a few days he had noticed small dark clots of blood in his sputum. Then he had become very short of breath and his feet had begun to swell. On admission he was slightly cyanosed, and was suffering greatly from dyspnœa. The respirations were rapid and shallow. On account of the loud rapid breathing physical examination was unsatisfactory, but an obstructive murmur at the mitral valve was discovered, and moist râles were heard over both lungs. On the eighth day after admission, he became delirious, but remained in this state only a few hours. At this time there was cyanosis more marked. The respirations were regular, but rapid and shallow. The apical impulse was in the sixth interspace in the nipple line, and was irregular in force and rhythm. A well-marked purring thrill was felt. The area of cardiac dulness was continuous with dulness over the lower lobe of the left lung. There was a presystolic murmur, with maximum intensity at the apex. The sounds at the other valves were normal. The respiratory murmur was absent over the lower part of the left lung, and there was distinctly tubular breathing. Pleuritic friction sounds were heard over the right lung, and here and there were a few fine moist râles. The patient died in a few hours from the time of this examination.

The autopsy was made forty-eight hours after death. The body was well developed and of medium size, but poorly nourished. The brain was normal. The left pleural cavity was obliterated by firm old adhesions. There was a slight excess of fluid in the right pleural cavity, but there were no adhesions. The pericardium was tense, and was slightly displaced downward and to the left by the adherent lung. There was a normal amount of serous fluid in the pericardium. There was a thrombus in the left pulmonary artery, just below the point at which the first large branch is given off. About half of the lower lobe of this lung was consolidated, and on section presented the appearance of an infarction. There were congestion and œdema in the upper lobe. The right lung showed two small circumscribed areas of fibrinous pleurisy which corresponded to two small infarctions. In the other parts of this lung there were marked congestion and œdema. The liver weighed three pounds six ounces, was firm, dark red in color, and on section showed the nutmeg appearance of passive hpyeræmia. The spleen weighed six ounces, was soft, pale blue in color, and in its anterior border presented a deep, congenital fissure in which was attached a part of the omentum. The kidneys weighed seven ounces each; the capsule was not adherent, and left a smooth surface on removal. The markings were distinct, the cortex was slightly swollen, and the pyramids were congested. The stomach and intestines were congested. All the cavities of the heart were distended with dark, partially clotted blood, but no firm clots were found. There were great dilatation of the left auricle and slight dilatation of all the other cavities. The walls were pale and rather soft. The tricuspid and pulmonary valves were normal. The

mitral valve would admit only the end of one finger; its cusps were greatly thickened and there were adhesions in the angles between the cusps. In one angle there was a calcareous deposit. The aortic valve had only two segments, an anterior and a posterior, both of which were very thick. The segments were of nearly equal size, the anterior being slightly longer. About the middle of the base of the anterior segment was a small constriction, which caused a slight puckering, but which did not involve the free border. At a point in the aorta which corresponded to the centre of this segment there was a distinct ridge, which seemed to mark the place where a third segment should have been attached. There was a calcareous plaque near the left end of the posterior segment, which did not extend to the free border or the aortic attachment. The sinuses of Valsalva were pouched out. Both coronary arteries were given off from the anterior sinus. There were a few atheromatous patches in the aorta at the upper margin of the sinuses. The valve was quite competent. When freed from blood, the heart weighed fourteen ounces.

The history and the appearance of the specimen, Dr. Shelby said, seemed to warrant the conclusion that this was a congenital affection, probably due to disease during intra-uterine life; and that the absence of one of the segments was caused by the coalescence of two segments at the time of their formation. The specimen illustrated the fact that a valve of this type might be entirely competent and yet have only two segments. It seemed clear that the lesion at the mitral orifice caused all the symptoms. The nearly equal size of the segments showed the wonderful adaptability of these segments to each other. After two small segments had united to form this large anterior segment, the posterior segment appeared to have undergone extra development to meet the requirements of its fellow. The unusual thickness of both aortic and mitral valves, and the calcareous deposits in them, would indicate that there had been during extra-uterine life a chronic endocarditis, but he thought there could be no doubt that the primary lesion had started *in utero*.

Adeno-Carcinoma of the Kidney; Total Thrombosis of the Vena Cava.—Dr. James Ewing presented a kidney which had been removed from a German, forty-eight years of age. The patient gave a phthisical family history, and a personal history of excessive indulgence in alcohol and of syphilitic infection in his youth. Ten months before his death he had noticed a swelling of the legs and feet, associated with headache and vomiting. Urination was then normal. The symptoms disappeared after a short time but returned four months later, and then the urine was at times scanty and bloody, and he had severe pain in the kidney and on urinating. After three weeks these subsided. Six weeks before his admission to the hospital they reappeared, and in addition the abdomen began to swell. The stools were light colored; the superficial abdominal veins were considerably distended. There was no abdominal pain; very slight ascites. The urine was alkaline, had a specific gravity of 1.024, and contained five per cent. of albumin and a few blood cells, but no sugar. Physical examination showed a slight quantity of fluid in the chest, with œdema of the lungs; the heart was normal; the spleen was not palpable. While he was in hospital there were no urinary symptoms, but he developed symptoms of obstruction to the portal circulation and to the venous return from the lower limbs. The distention of the abdominal wall was the chief feature clinically. It was thought that there was probably a thrombosis of the portal or mesenteric vein. He was tapped, but this was followed by peritonitis and death in forty-eight hours. At the autopsy, the chamber of the right auricle showed at the opening of the inferior vena cava a round whitish mass, looking like a blood clot. There was no endocarditis. There was also a partially necrotic mass in the region of the vena cava, behind the liver. The vena cava was distended to the diameter of nearly three inches at this point, and was entirely occluded by a large mass of tumor tissue, which proved to have been derived from the original tumor in the kidney. The right kidney showed the appearances of carcinomatous or adenomatous growth arising in the cortex, projecting into the pelvis and infiltrating the tissue around the renal, and passing up the renal veins to the vena cava, where it had grown rapidly. A completely organized thrombus was found in the vena cava below the kidney, reaching into the iliac veins and extending below Poupart's ligament. Another interesting feature was the apparent reconstruction of the circulation through the intestines, spleen, and left kidney, as these organs showed very little venous congestion. The hepatic vein and its smaller branches were occluded by freshly clotted blood. The liver, of course, was extremely congested, but the other abdominal organs were only very moderately so. Another point of interest was the fact that the patient had survived a total thrombosis of the vena cava, this thrombosis having apparently existed for five weeks.

Hæmato-Myelopore.—Dr. Ira Van Gieson presented a specimen from one of the cases of hæmatomyelopore described by him at the last meeting, and demonstrated the columnar lesion found in the spinal cord.

The society then went into executive session.

Radical Cure of Congenital Hydrocele.—M. Mencière (*Arch. Clin. de Bordeaux*, No. 6, p. 283, 1897) publishes his observations on two patients affected with congenital hydrocele, upon whom M. Demons employed an operative procedure which has given satisfaction. The operation consists in making a long incision following the greater axis of the tumor; that is to say, from above downward, the incision reaching to the inguinal ring. When he comes to the serous portion he incises it freely according to the method of Volkmann, then he destroys the peritoneo-vaginal sac, cutting it transversely with the aid of scissors. The edges of the serous sac thus formed are brought together and sutured with catgut, in such a way that the testicle is contained in a reconstructed vaginalis, less extended than the former. From below this new vaginalis he excises the serous coat to a certain height, so that the peritoneo-vaginal canal is incontestably destroyed. Then, considering the superior part of this canal as a hernial sac, he procedes with a truly radical cure of hernia. Thus the inguinal ring is closed, the portion of the peritoneo-vaginal canal situated immediately beneath is excised, and the testicle is contained in a new vaginal cavity having no communication with the abdominal cavity. This method differs from that described by Faure, in which the operator is content to open the vaginalis and trust to an adhesive inflammation to obliterate the peritoneo-vaginal canal. Here the surgeon not only obliterates the canal, but closes the inguinal ring. Instead of leaving the vagi-

nalis to mend itself, some sutures of fine catgut reconstruct it immediately. The operator can reconstruct the vaginalis and afterward close the inguinal ring. In cases of congenital hydrocele, it is preferable first to close the inguinal ring and then proceed with the repair of the vaginal cavity.
